

# The role of soil moisture in the West African monsoon

*Alexis BERG*

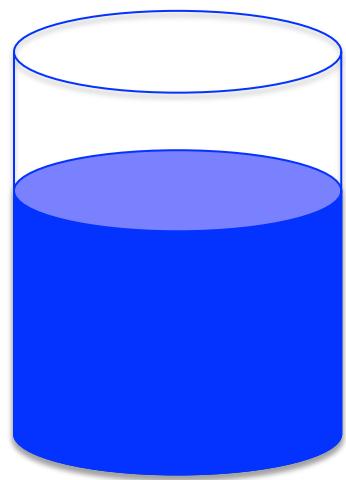

*NSF postdoctoral Fellow*

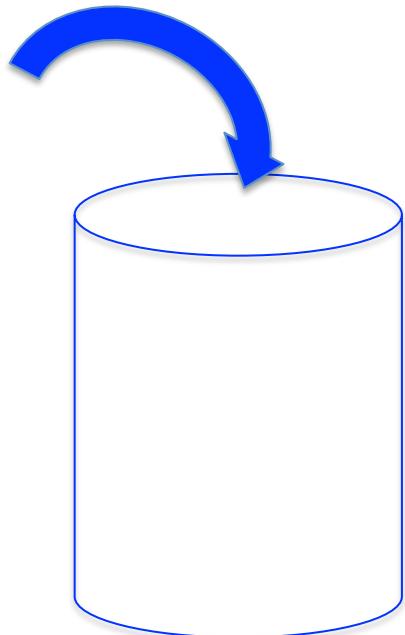

*International Research Institute for Climate and Society @ Columbia University*

*With: A.Giannini (IRI), B. Lintner (Rutgers Univ.), K. Findell (GFDL), M. Biasutti (LDEO)  
and GLACE-CMIP5 participants.*

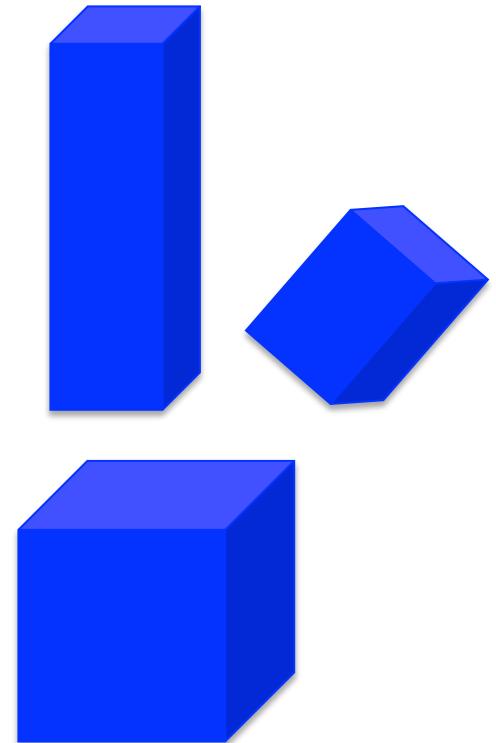

## Some perspective: land surface processes

Theory: Glass (more than) half full

Observations: Glass nearly empty but the server is pouring

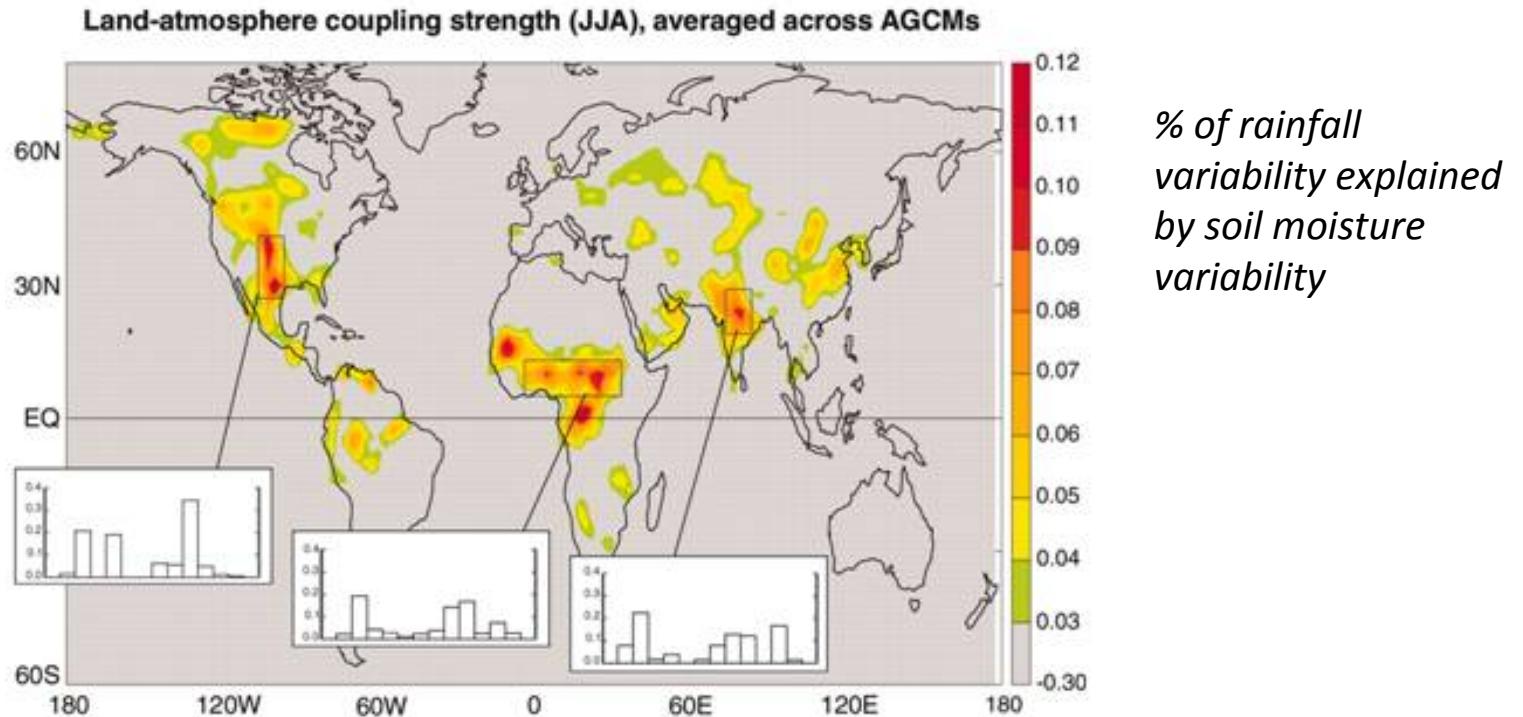

Models

## Motivation

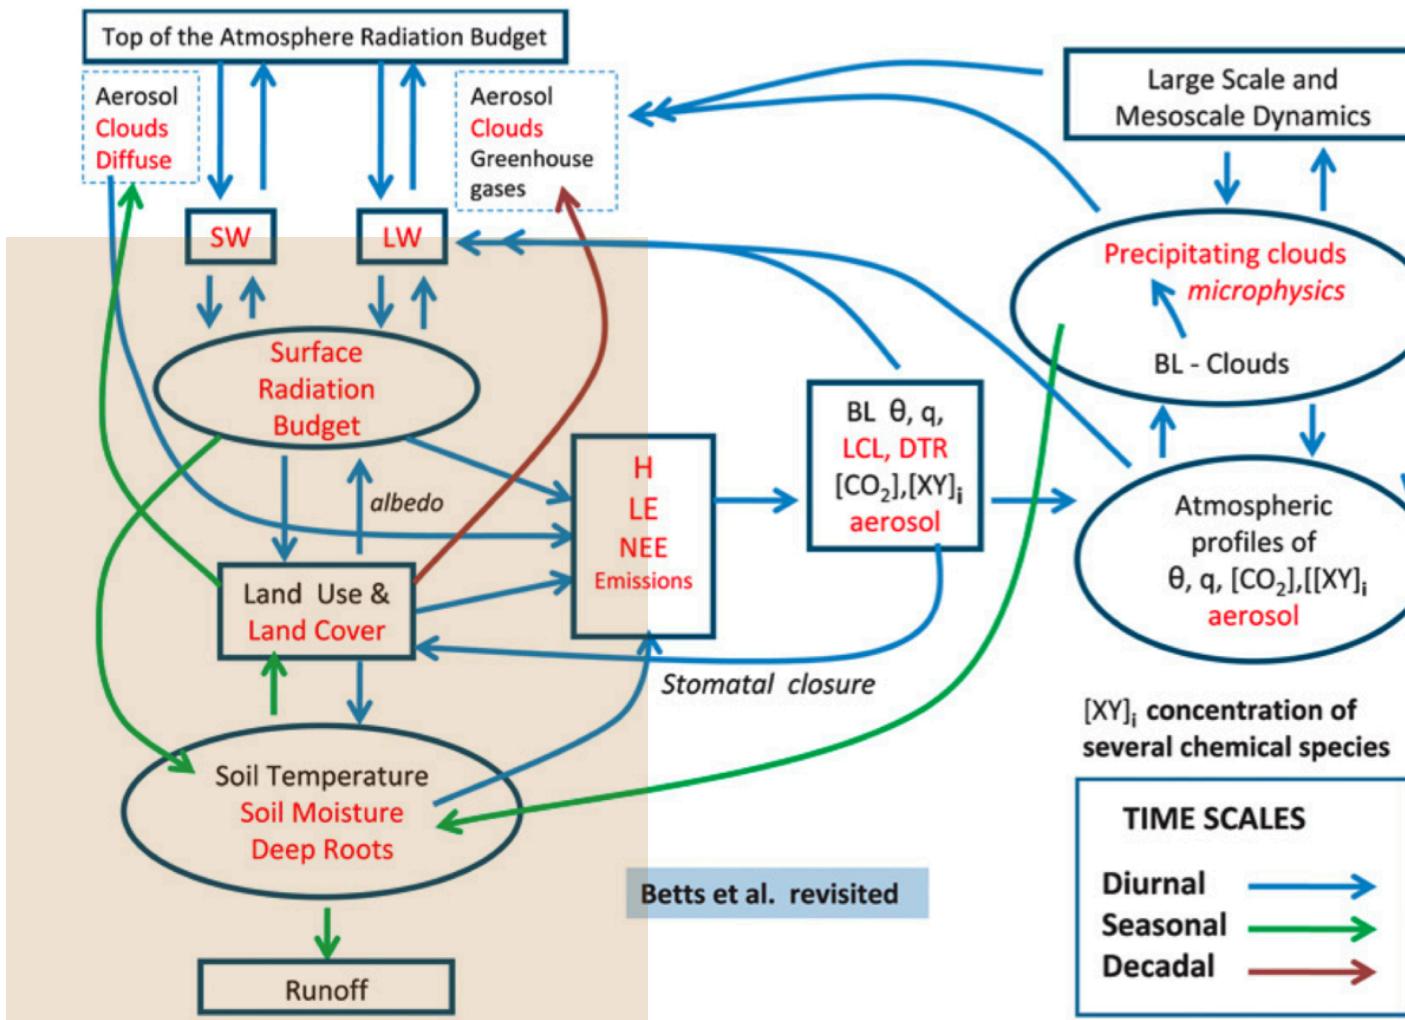

- West Africa has been identified as a “hotspot” of soil moisture-atmosphere coupling (**Koster et al. 2004**).
- **How do land-atmosphere (LA) interactions behave in monsoonal regimes?**
- *Shifting seasonality under future climate change [M. Biasutti]*

Experiment  
comparing AMIP –  
style seasonal runs  
with prescribed and  
interactive soil  
moisture (JJA 1994)

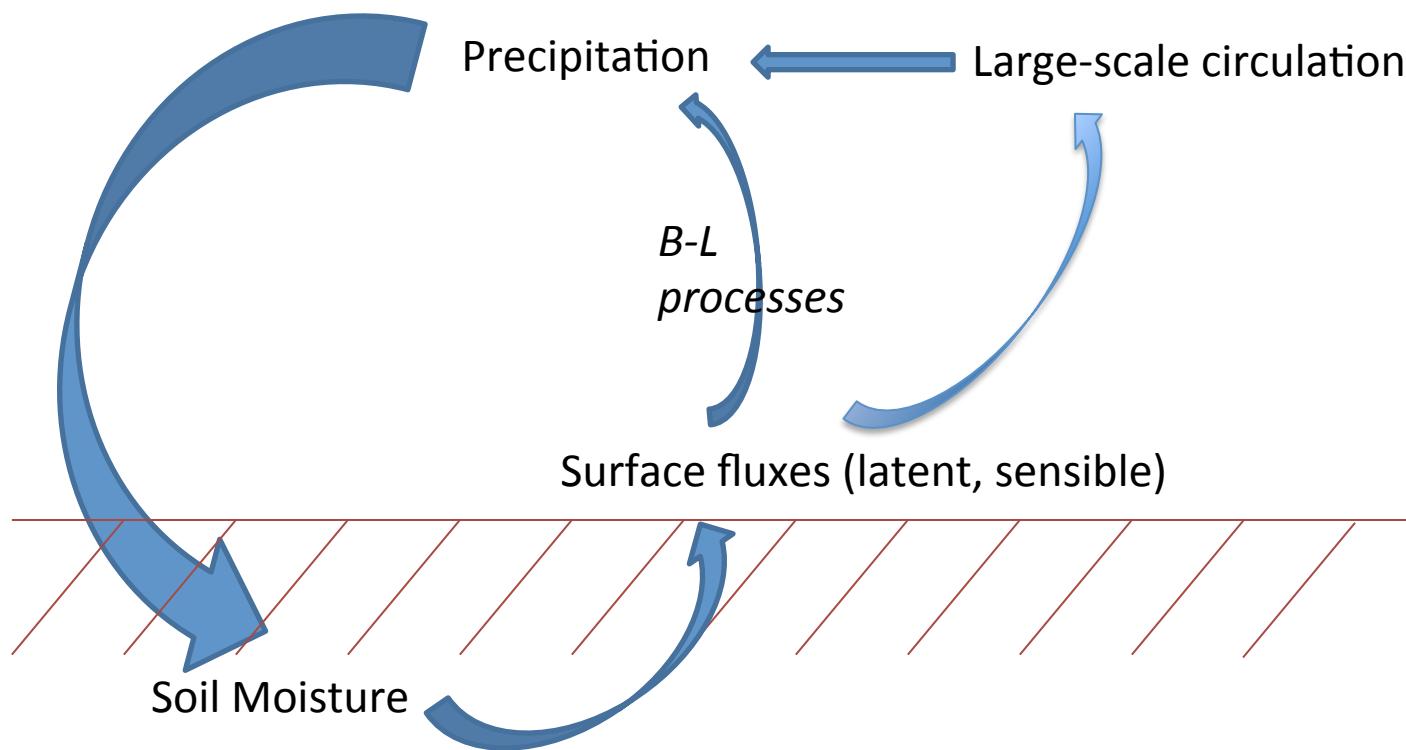

# Schematic of LA Interactions

*(Betts and Silva Dias 2010)*

## A simplified view

## Methodology

Climate model simulations with interactive / prescribed SM from GLACE-CMIP5  
*(Seneviratne et al. 2013, Geophys. Res. Lett.)*

- 6 GCMs (ACCESS, ESM2M, MPI-ESM, EC-EARTH, CCSM4, IPSL-CM5A)
- 1951-2100 transient simulations: Historical + RCP8.5 (concentrations)
- SSTs prescribed from corresponding ‘parent’ CMIP5 coupled simulation

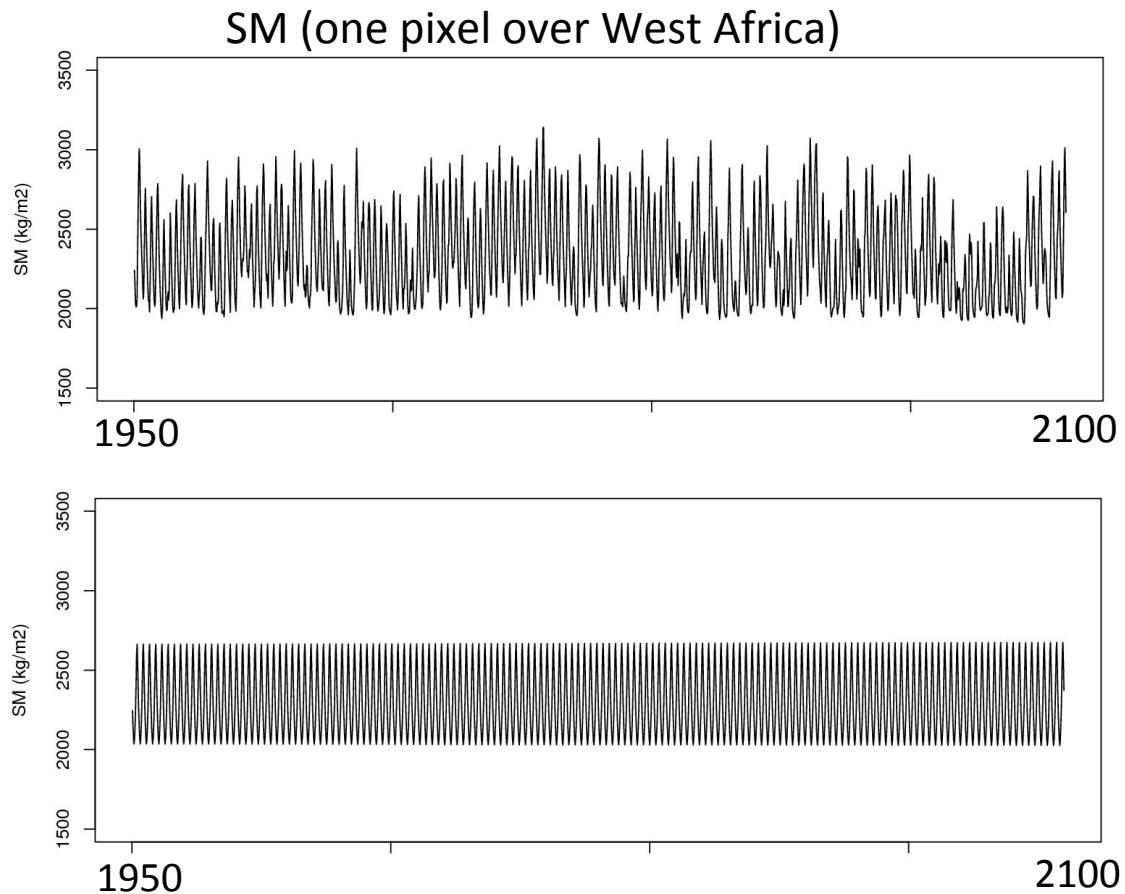

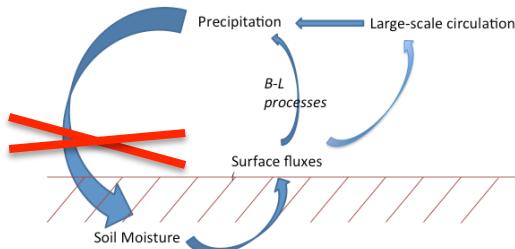

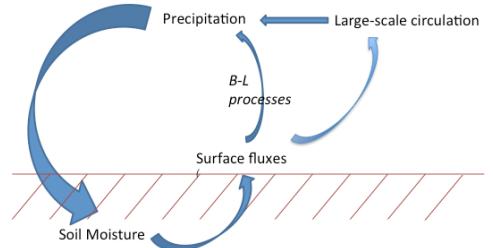

Simulation **INT**: **interactive** soil moisture

Simulation **FIX**: soil moisture prescribed to **1971-2000 climatological seasonal cycle** from corresponding parent CMIP5 simulation

- Caveat: **FIX** simulations do not conserve total water.

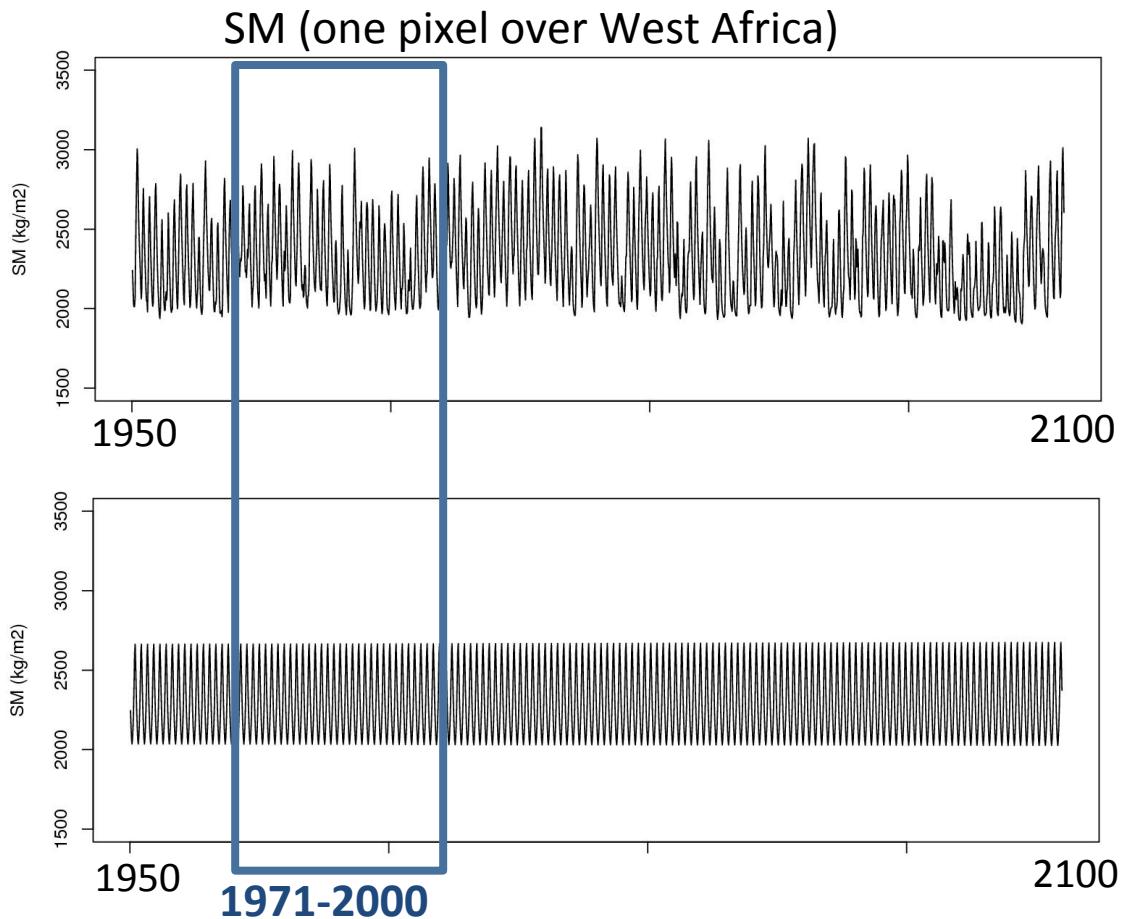

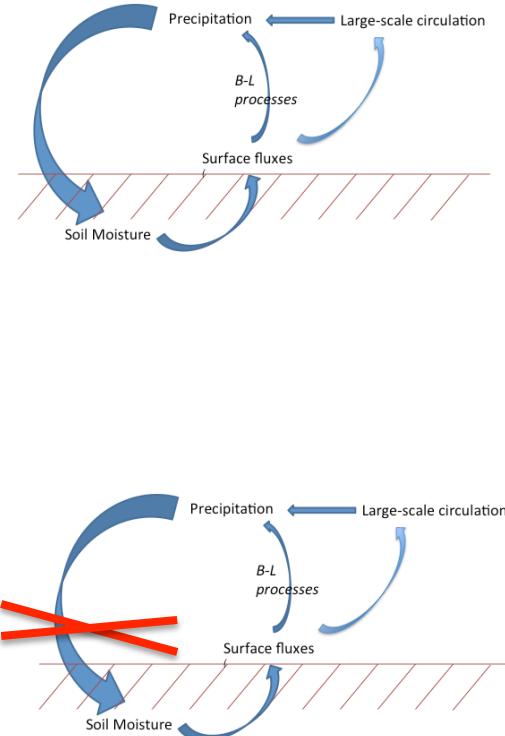

# The GLACE Approach

Climate model simulations with interactive / prescribed SM from GLACE-CMIP5

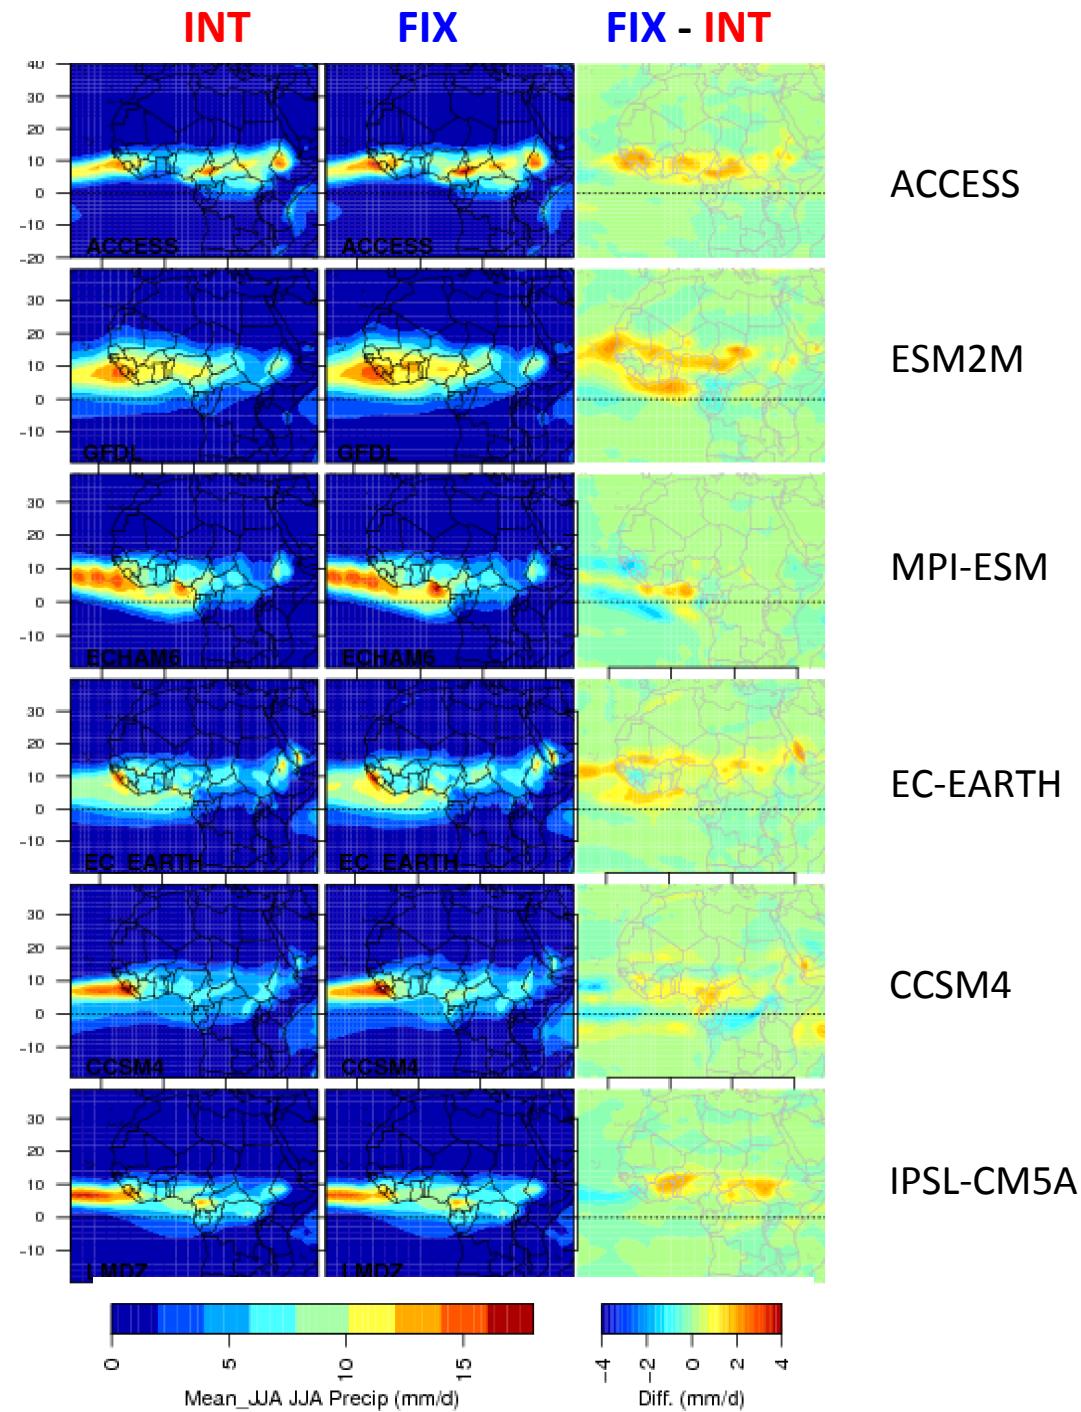

# Methods

Climate model simulations with interactive / prescribed SM from GLACE-CMIP5

We compare both simulations over 1971-2000.

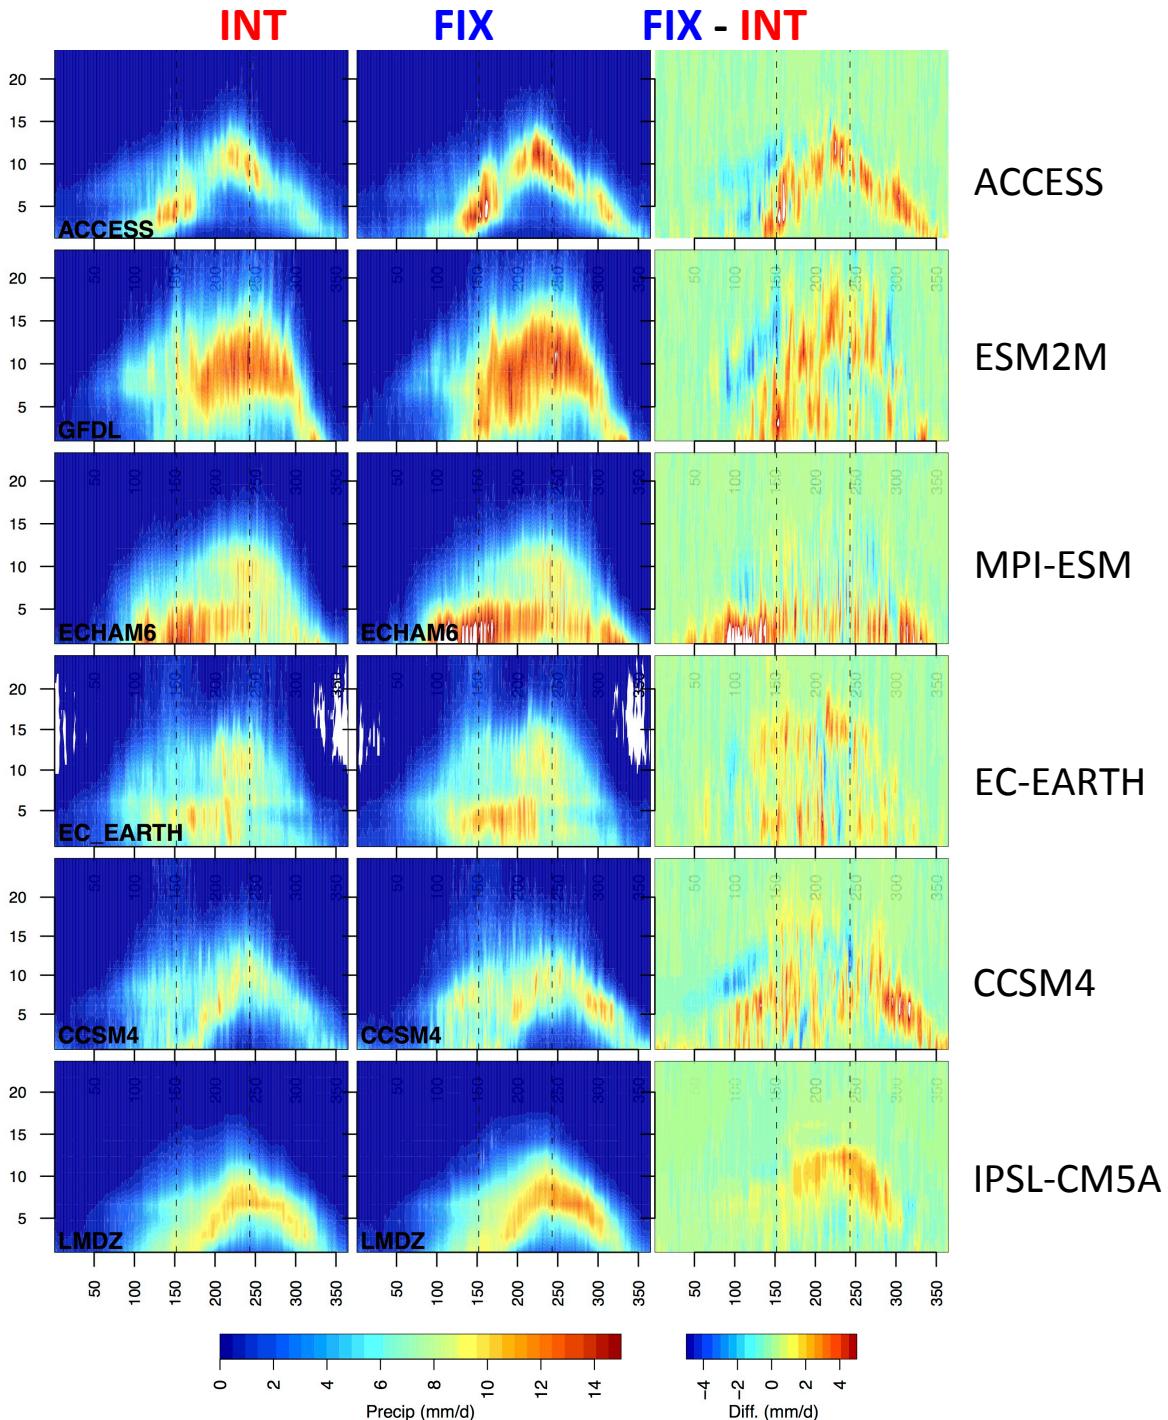

*Mean JJA precipitation over  
1971-2000*

**Mean JJA precipitation over  
1971-2000**  
**Time-latitude view over  
10W-10E**

In **4/6 models**, mean rainfall intensity in the “core”/toward the end of the monsoon season in **FIX**.

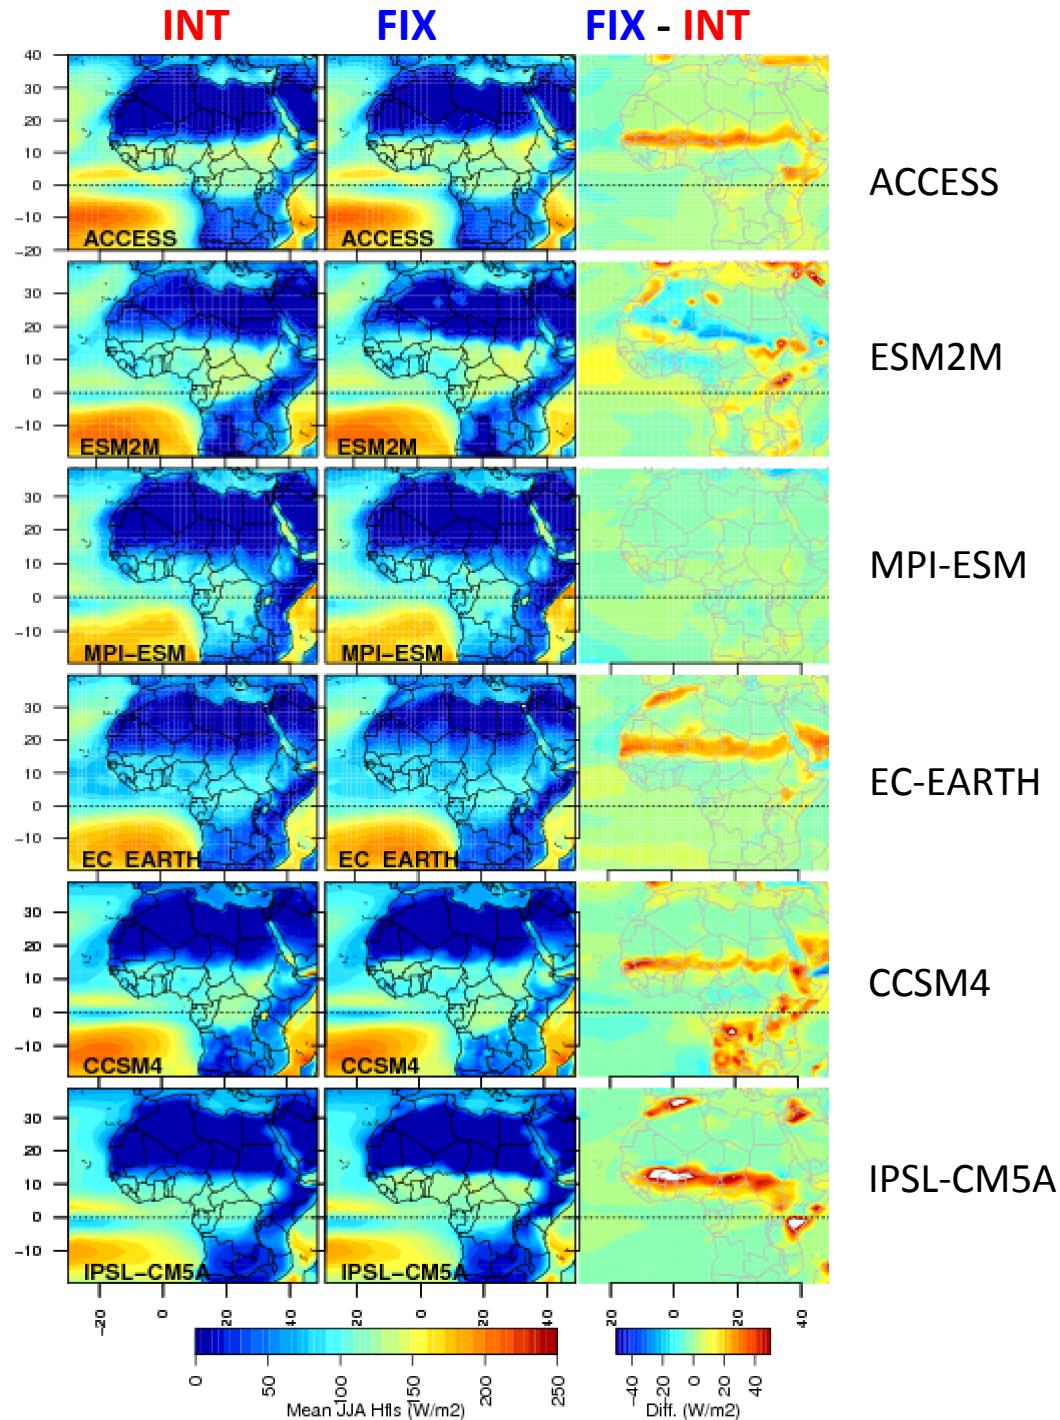

In **3/6 models**, rainfall intensity is reduced in the early monsoon season (April, May) in **FIX**.

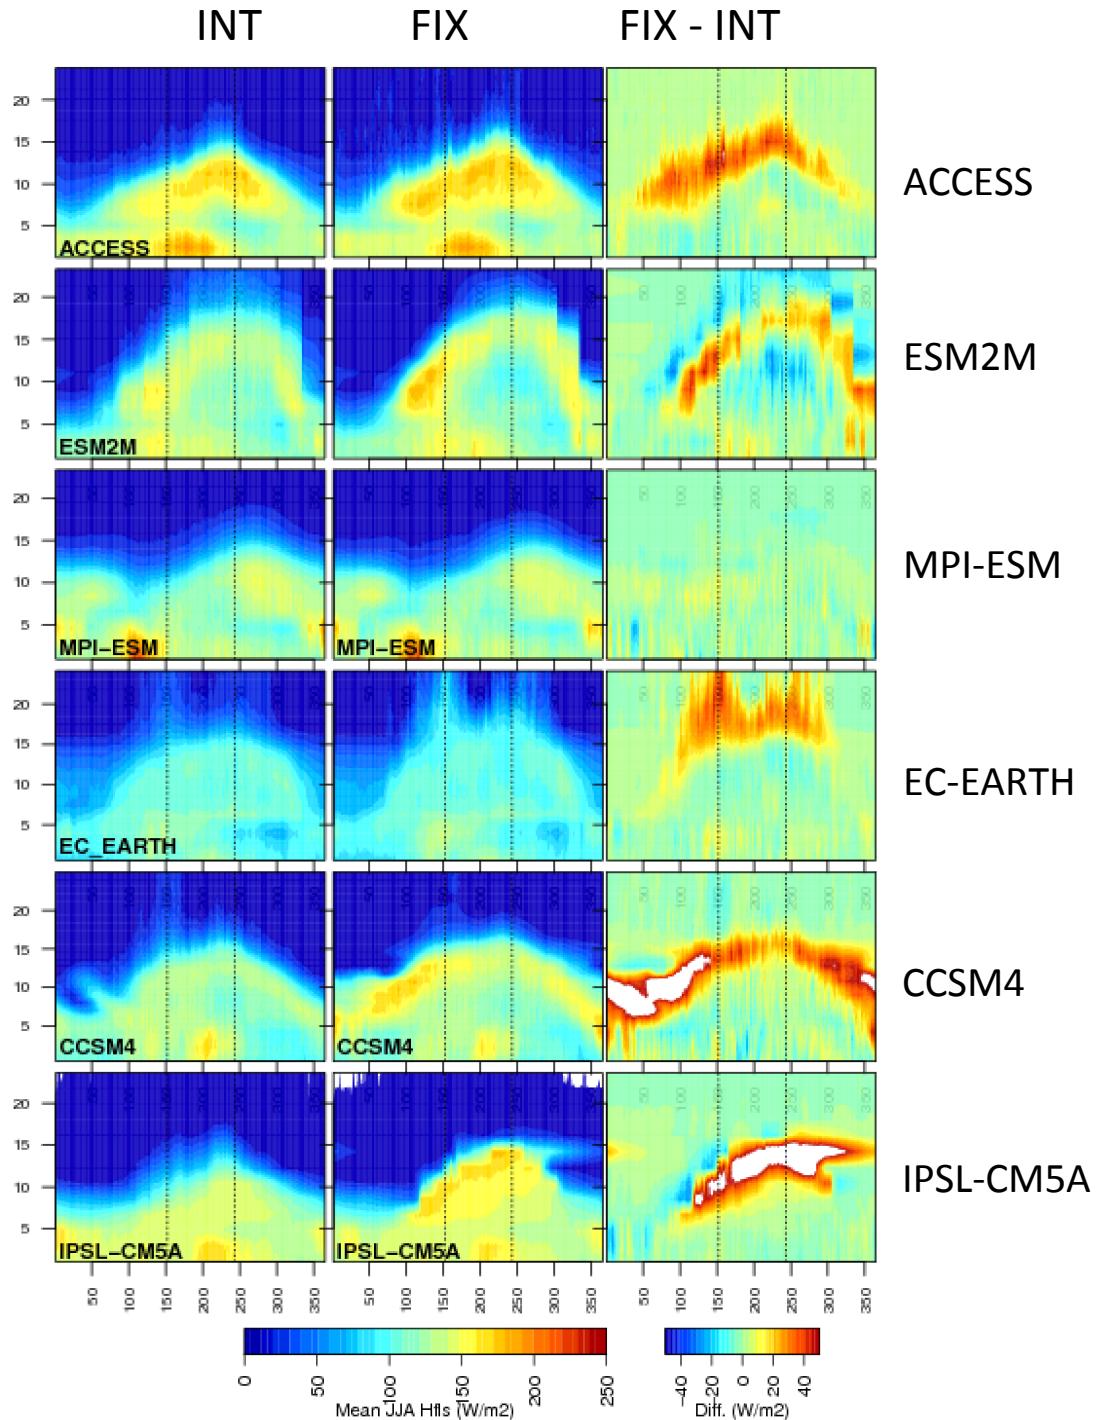

**Mean JJA surface latent  
heat flux  
1971-2000**

In **5/6 models**, mean JJA evaporation is enhanced along the poleward (dry) margin of the monsoon in **FIX**.

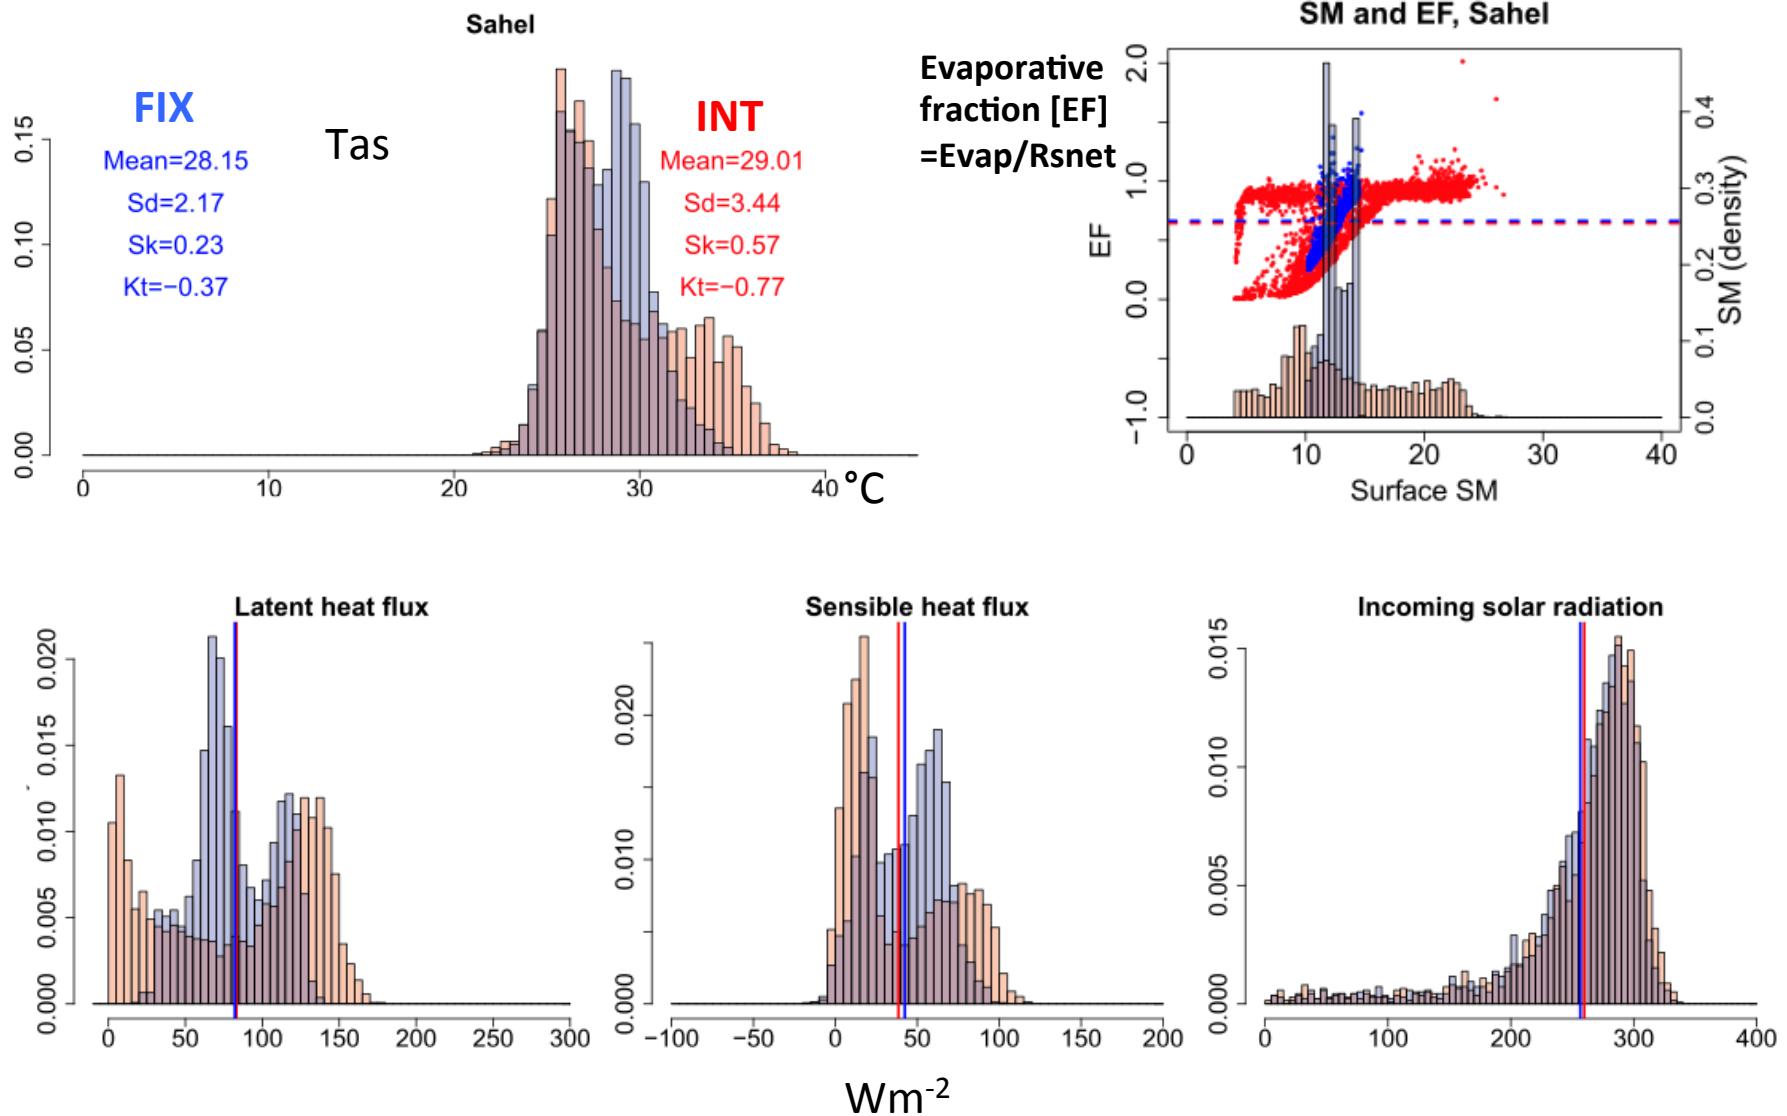

*This enhanced evaporation is not caused by increased rainfall in **FIX**.*

*Mean JJA surface latent  
heat over 1971-2000  
Time-latitude view over  
10W-10E*

# *Why does prescribing climatological soil moisture lead to greater evaporation in dry regimes?\**

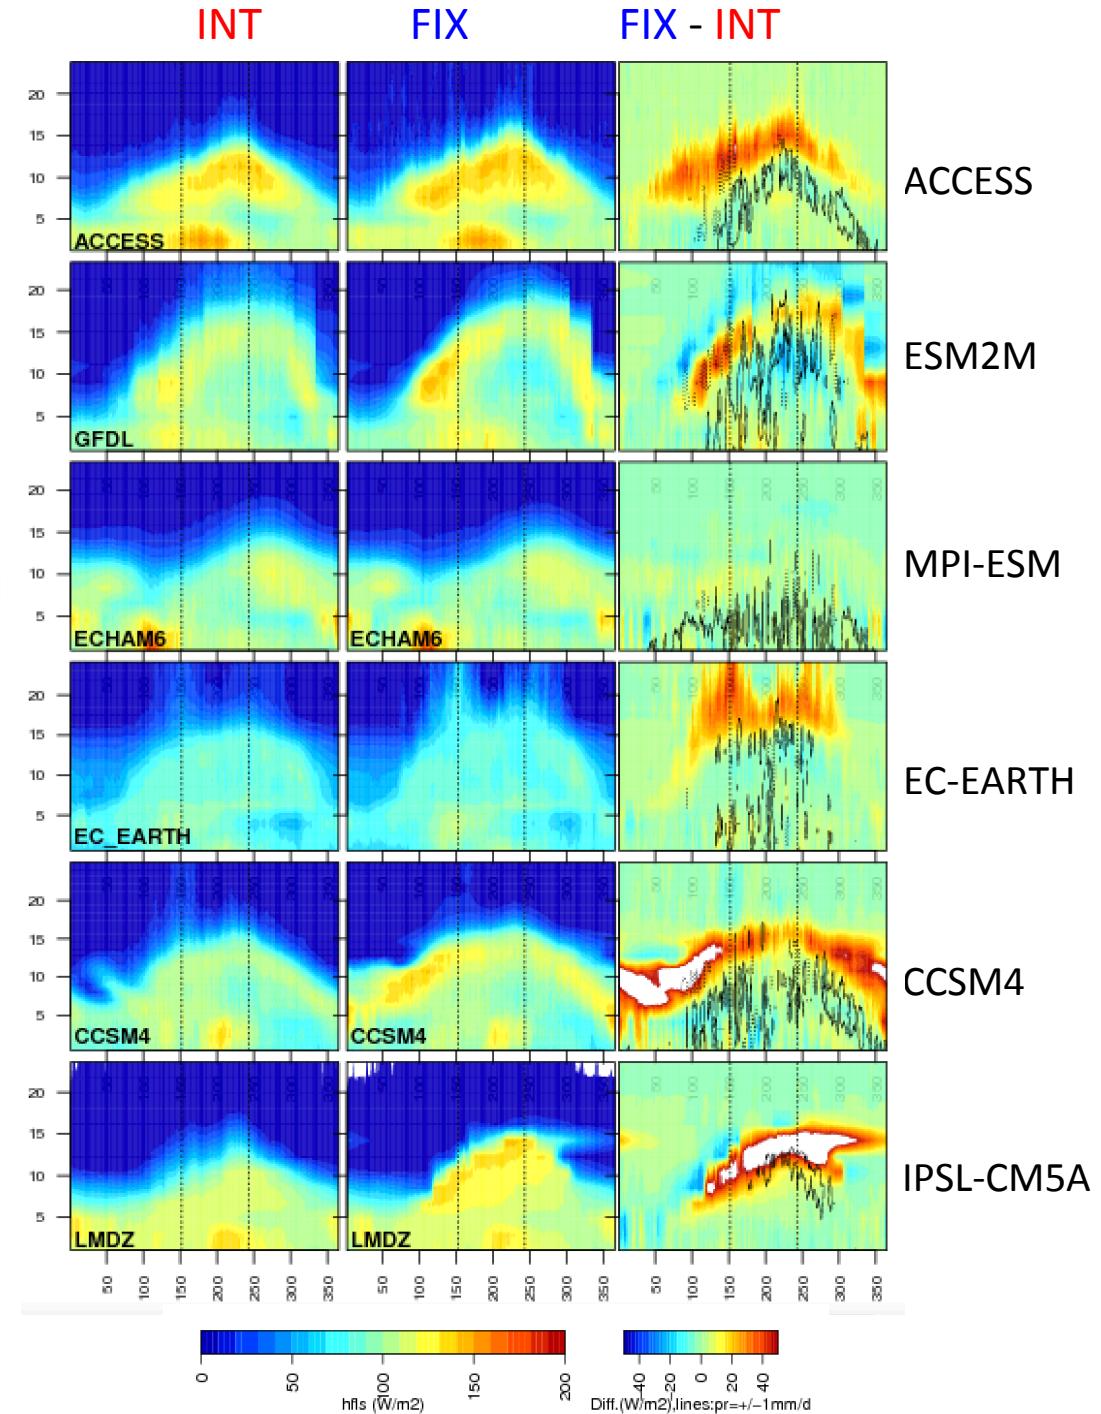

\*At least in the GFDL model

**Surface latent heat flux  
(shading) and precipitation  
(contours)**

During the core/late season monsoon, enhanced evaporation generally occurs poleward of enhanced rainfall in **FIX**.

In the early season, enhanced evaporation is generally co-located with reduced rainfall in **FIX**.

## **One possible core/late season: reduced dry air (or low MSE) ventilation**

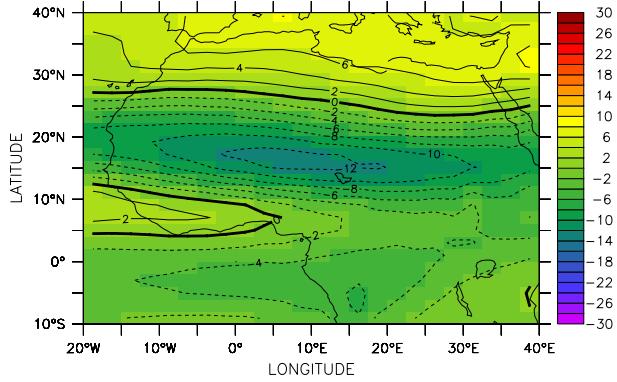

[Previous work by D. Neelin, H. Su, C. Chou; also talks by O. Pauluis and S. Hill]

Essentially, the poleward edge of the monsoon is ventilated by very dry air from the Sahara. In **FIX**, the enhanced evaporation moistens the influence, raising its MSE.

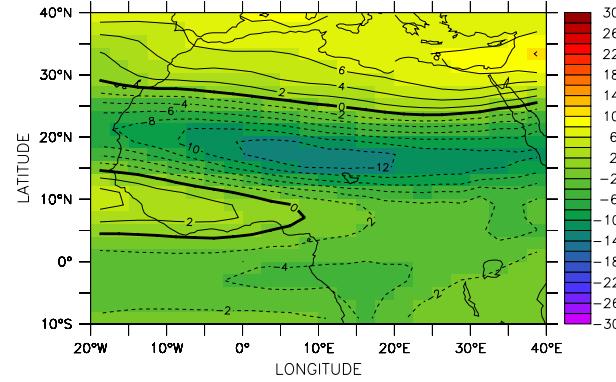

TBD: Moisture budget

# Core/Late Season: 600 mb Zonal Wind

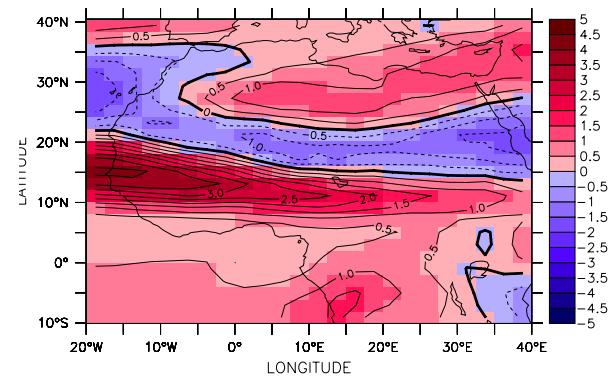

**Lon-Lat View**

ucomp, 600mb, August, 1971–2000, INT

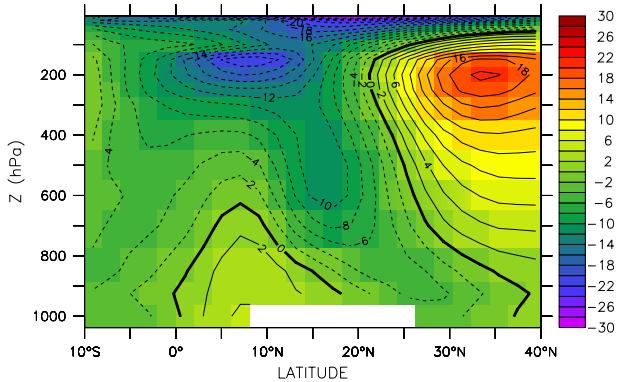

ucomp, 600mb, August, 1971–2000, FIX

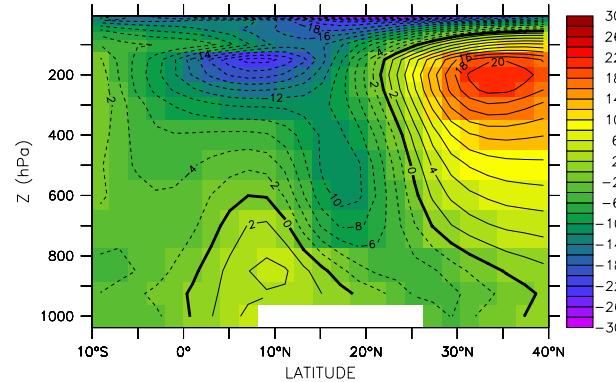

ucomp, 600mb, August, 1971–2000, FIX-INT

**Lat-Height View**

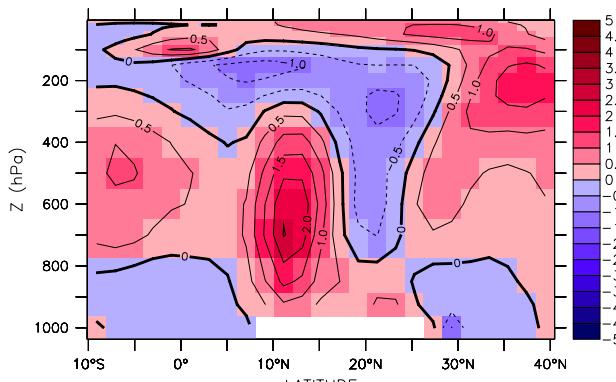

ucomp, August, 1971–2000, INT

**INT**

ucomp, August, 1971–2000, FIX

**FIX**

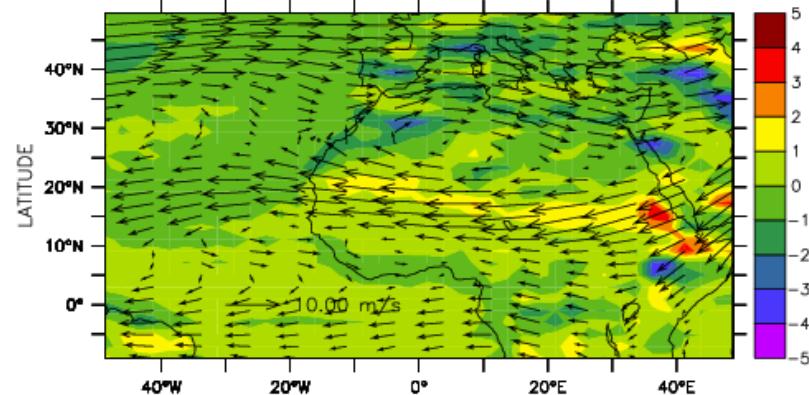

ucomp, August, 1971–2000, FIX-INT

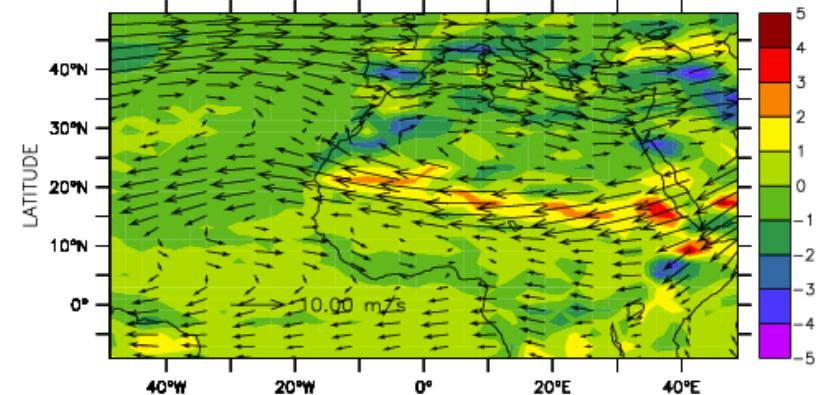

**FIX - INT**

The African Easterly Jet (AEJ) is shifted poleward in **FIX**.

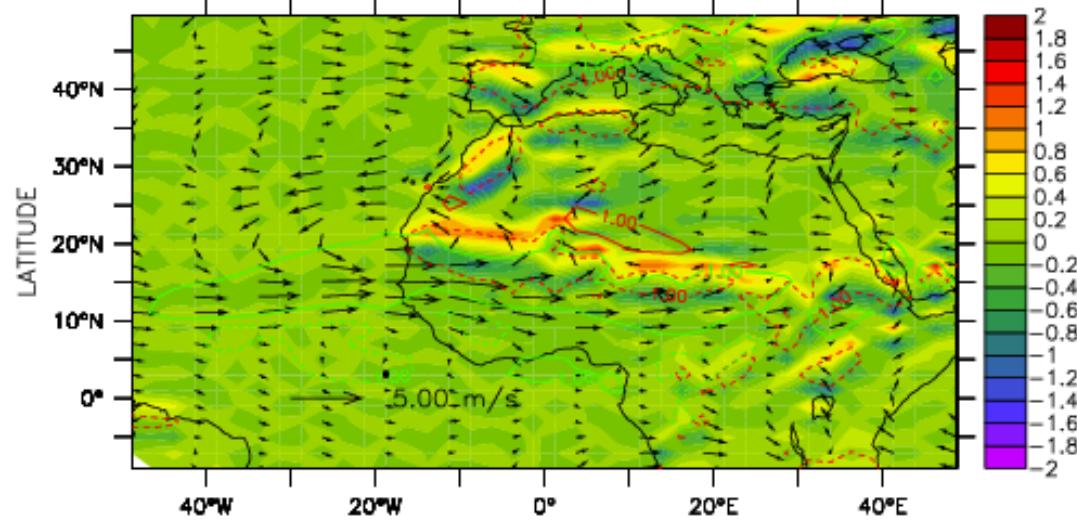

# Core/Late Season: 600 mb Zonal Wind and Surface Air Temperature

august, INT, merid. T grad(K/100km) and u600mb,1971–1990,GFDL

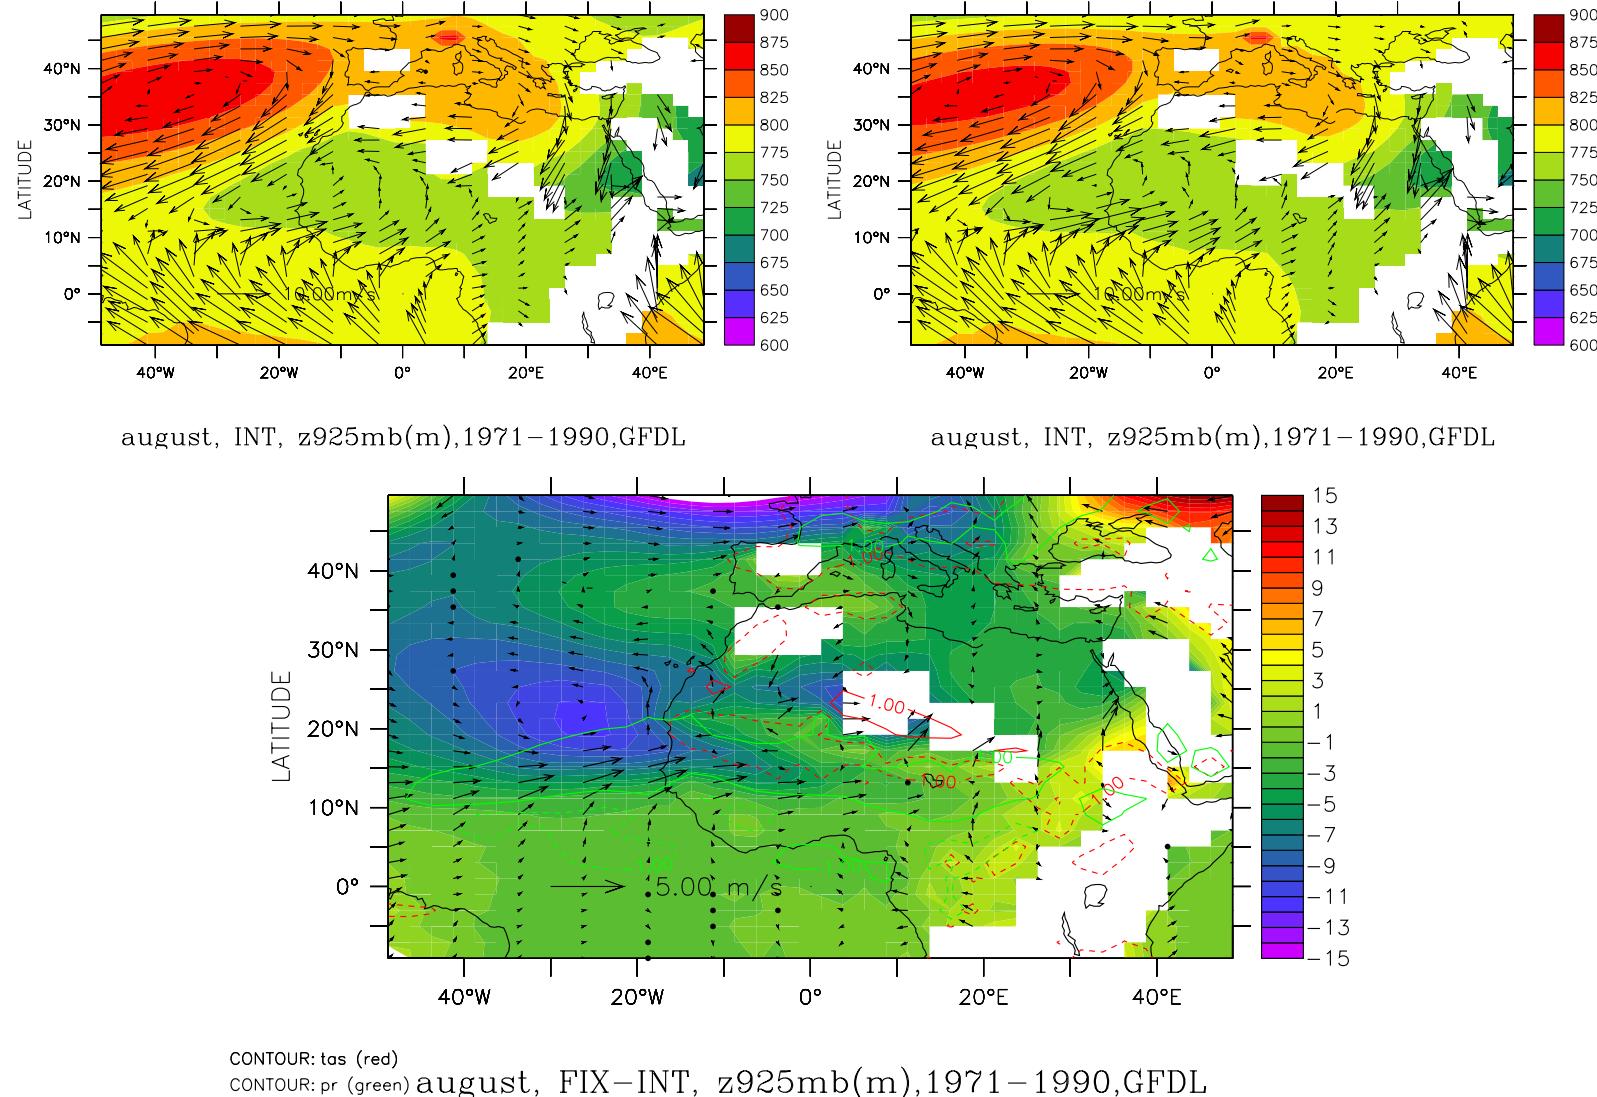

august, FIX, merid. T grad(K/100km) and u600mb,1971–1990,GFDL

CONTOUR: tos (red)    august, FIX-INT, merid. T grad(K/100km) and u600mb,1971–1990,GFDL  
CONTOUR: pr (green)

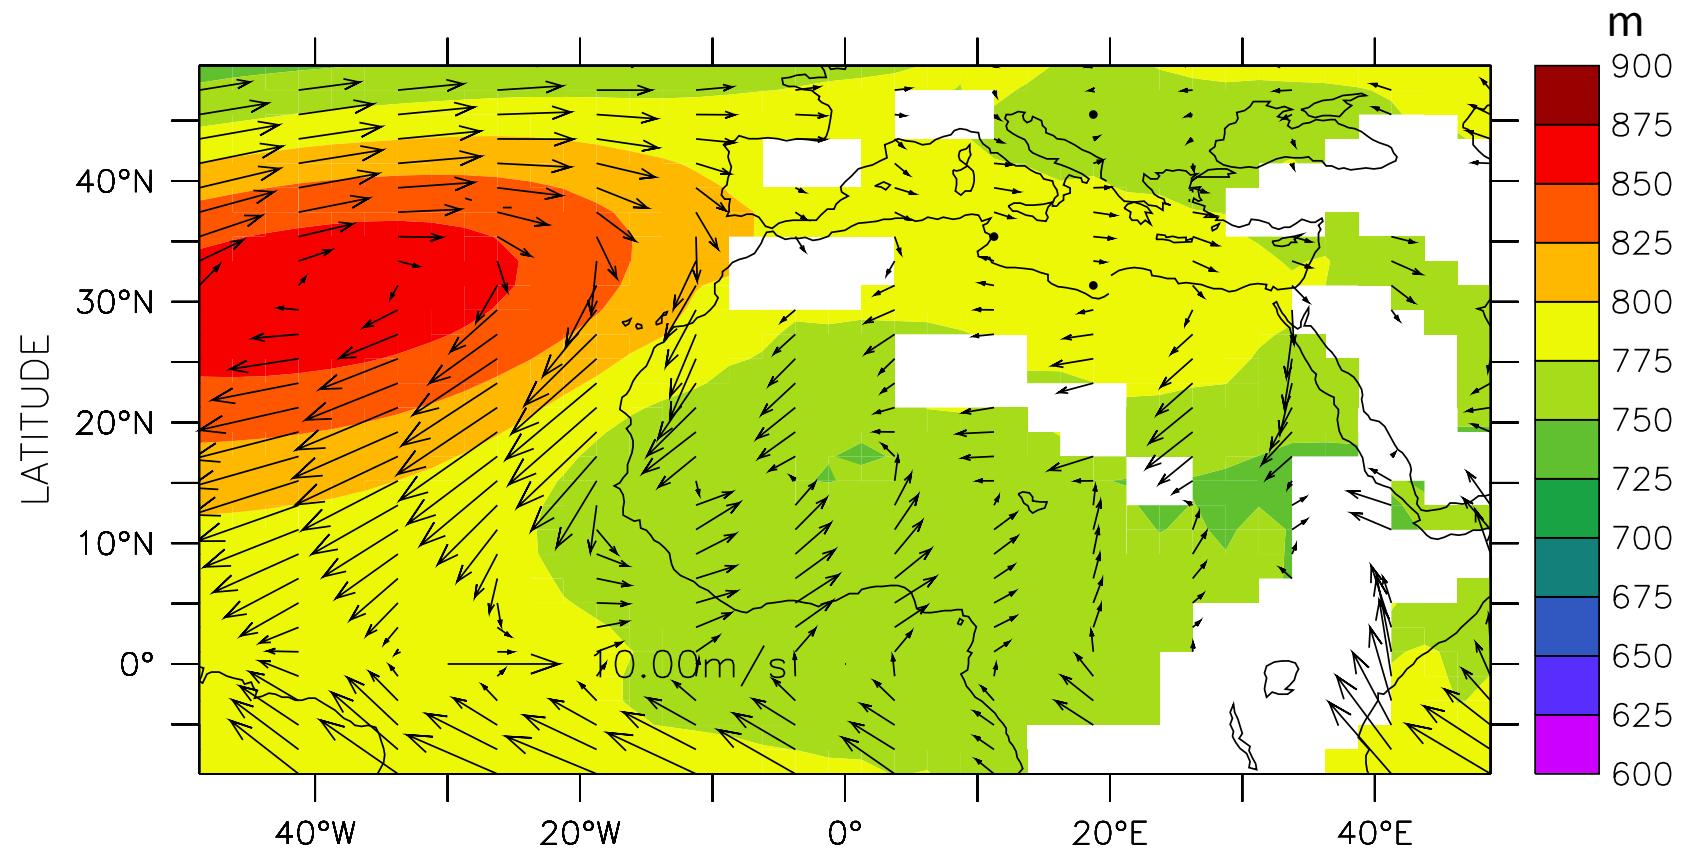

The poleward shift is consistent with a poleward displacement of the maximum surface temperature gradient.

# Core/Late Season: 925 mb Winds and Geopotential Height

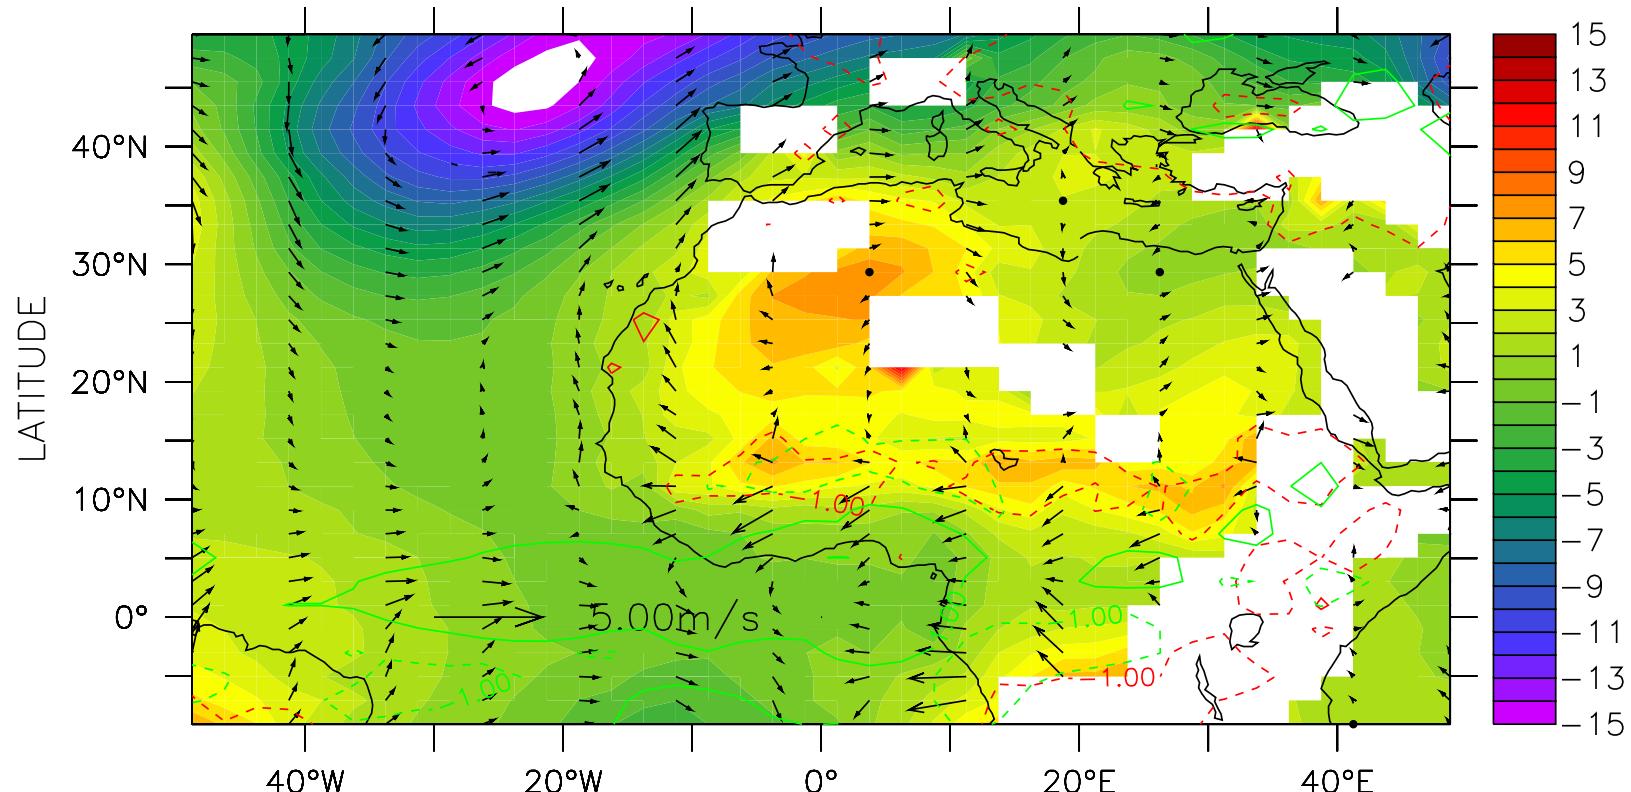

There is also an enhancement of low level westerlies.

**Early season:  
925mb Winds and Geopotential Height for May (INT)**

# Early season: 925mb Winds and Geopotential Height for May (**FIX** - **INT**)

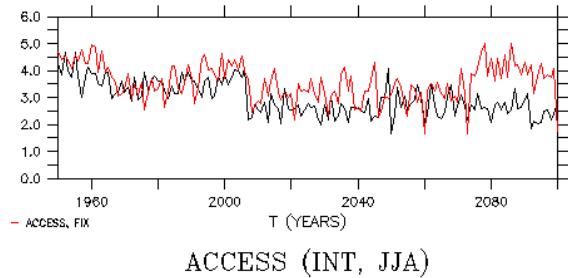

[Tas= red contours; Pr = green contours ]

Enhanced evaporation in **FIX** cools the near surface relative to **INT** and contributes to building high surface pressure over continent, suppressing monsoon onset.

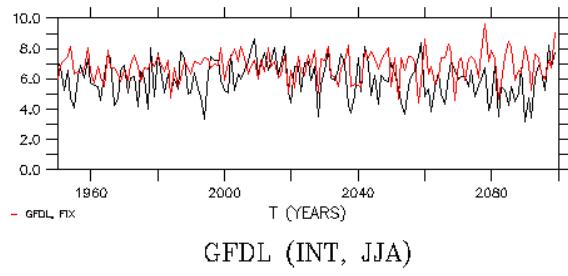

## Conclusions

- Model simulations suggest that the interactivity of soil moisture fundamentally influences the West African Monsoon.
- The apparent impacts vary over the course of the monsoon season:
  - *At the onset of the monsoon, interactive soil moisture may promote warming of the surface and the development of favorable land-sea contrast necessary to initiate the monsoon.*
  - *During the core of the monsoon, it seems to be more about the modulating effect of soil moisture and associated evaporation on dry air inflow and/or circulation changes associated with the AEJ and low-level westerlies.*
- A take home message here is that its not local recycling of enhanced evaporation but rather interplay of soil moisture and attendant surface changes with large-scale circulation - more reliable in models than local/ mesoscale soil moisture-convection feedbacks ? (cf. C.Taylor's work).
- Need to confirm processes in all participating models / understand model differences in precipitation response.

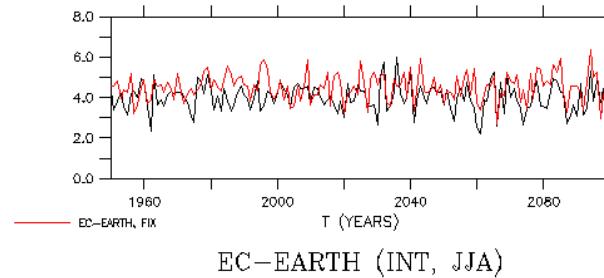

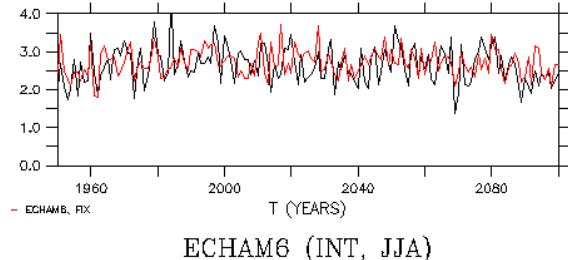

# Mean JJA Precipitation over the Sahel

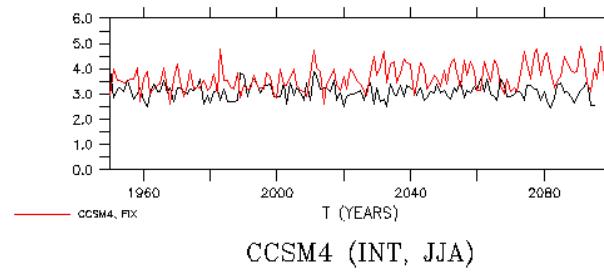

LONGITUDE : 15W(-15) to 30E  
LATITUDE : 9N to 20N

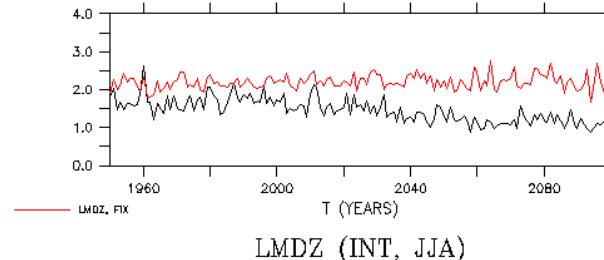

LONGITUDE : 15W(-15) to 30E  
LATITUDE : 9N to 20N

LONGITUDE : 15W(-15) to 30E  
LATITUDE : 9N to 20N

LONGITUDE : 15W(-15) to 30E  
LATITUDE : 9N to 20N

- A range of future projections in the control simulations.
- Simulations with prescribed late 20<sup>th</sup> century soil moisture tend to dry less in the future.
