Antarctic polynyas

Areas of open water
surrounded by sea ice

Can be identified with
SSM/I satellite data

Based on days of ice
cover

Red = Max

Blue = Min

Polynyas are blue
areas near coast

Antarctic polynyas

Hot spots of primary
production ($\text{g C m}^{-2} \text{ yr}^{-1}$)

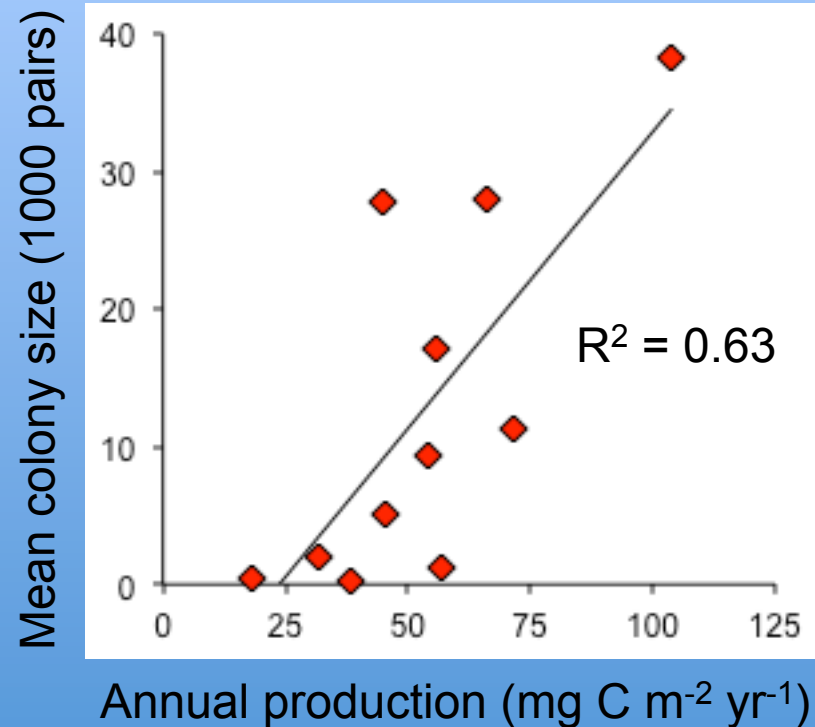

Antarctic polynyas

Hot spots of primary production ($\text{g C m}^{-2} \text{ yr}^{-1}$)

Can support high densities of marine mammals and birds

Adelie Penguins vs. Polynya Productivity

Arrigo and Van Dijken (2003)

Antarctic polynyas

Hot spots of primary production ($\text{g C m}^{-2} \text{yr}^{-1}$)

Can support high densities of marine mammals and birds

Seal Pups vs. Polynya Productivity

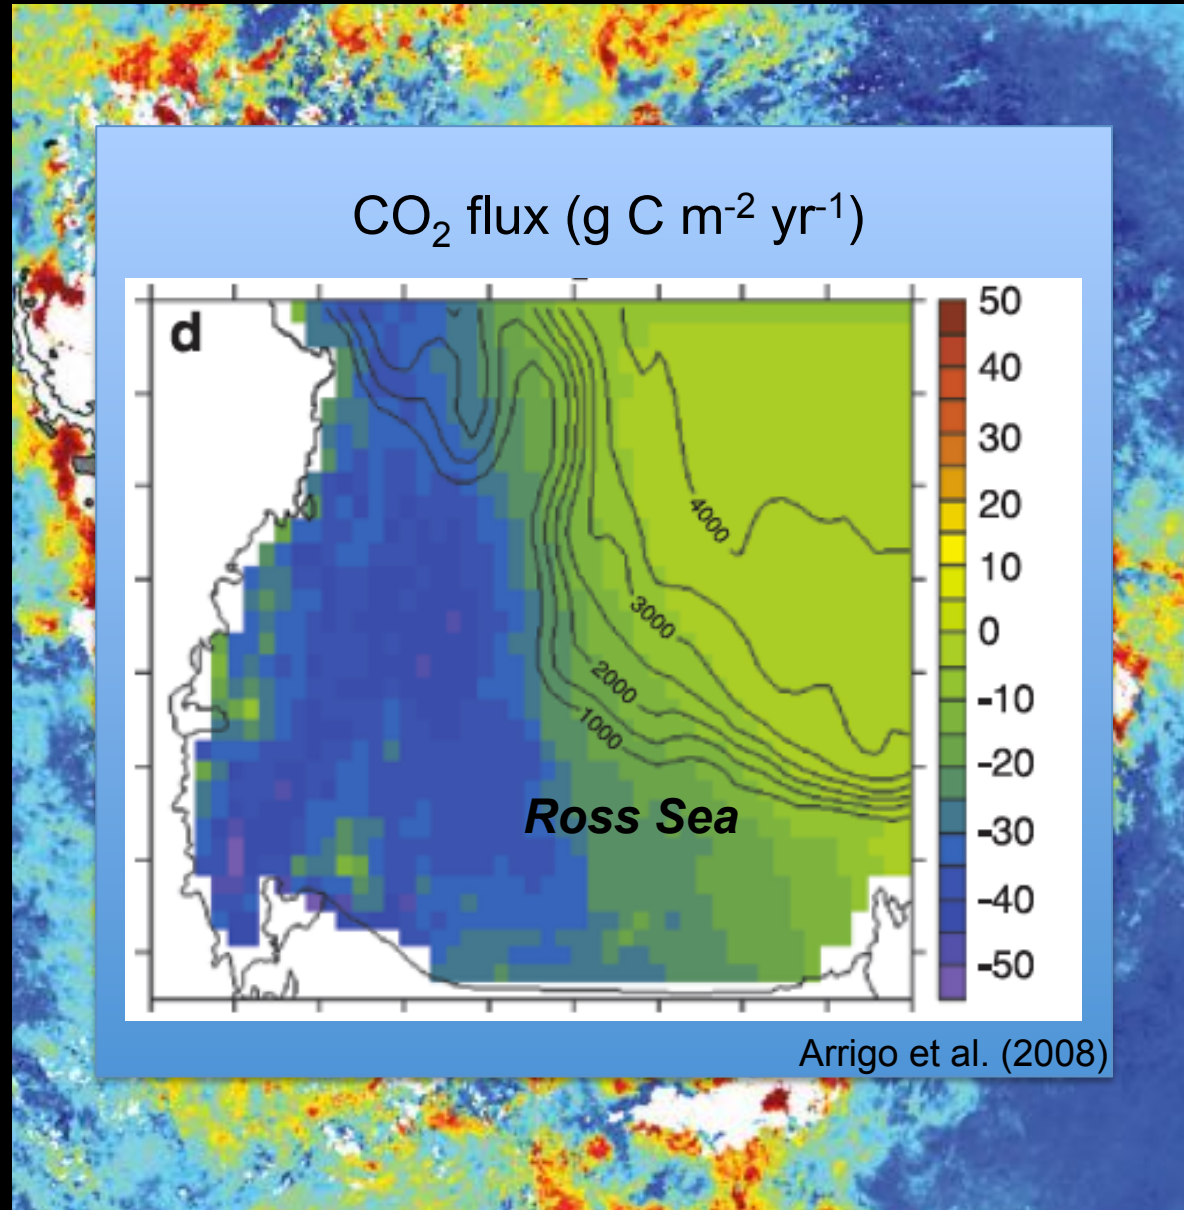

Paterson et al. (submitted)

Antarctic polynyas

Hot spots of primary production ($\text{g C m}^{-2} \text{yr}^{-1}$)

Can support high densities of marine mammals and birds

Large sinks for atmospheric CO_2

Question:

What factors control phytoplankton abundance in Antarctic coastal polynyas?

Factors investigated for each polynya:

Area of open water

Number of days of open water

Mean daily PAR during growing season

Sea surface temperature

Continental shelf width

Basal melt rate of nearby glaciers (Rignot et al. 2013)

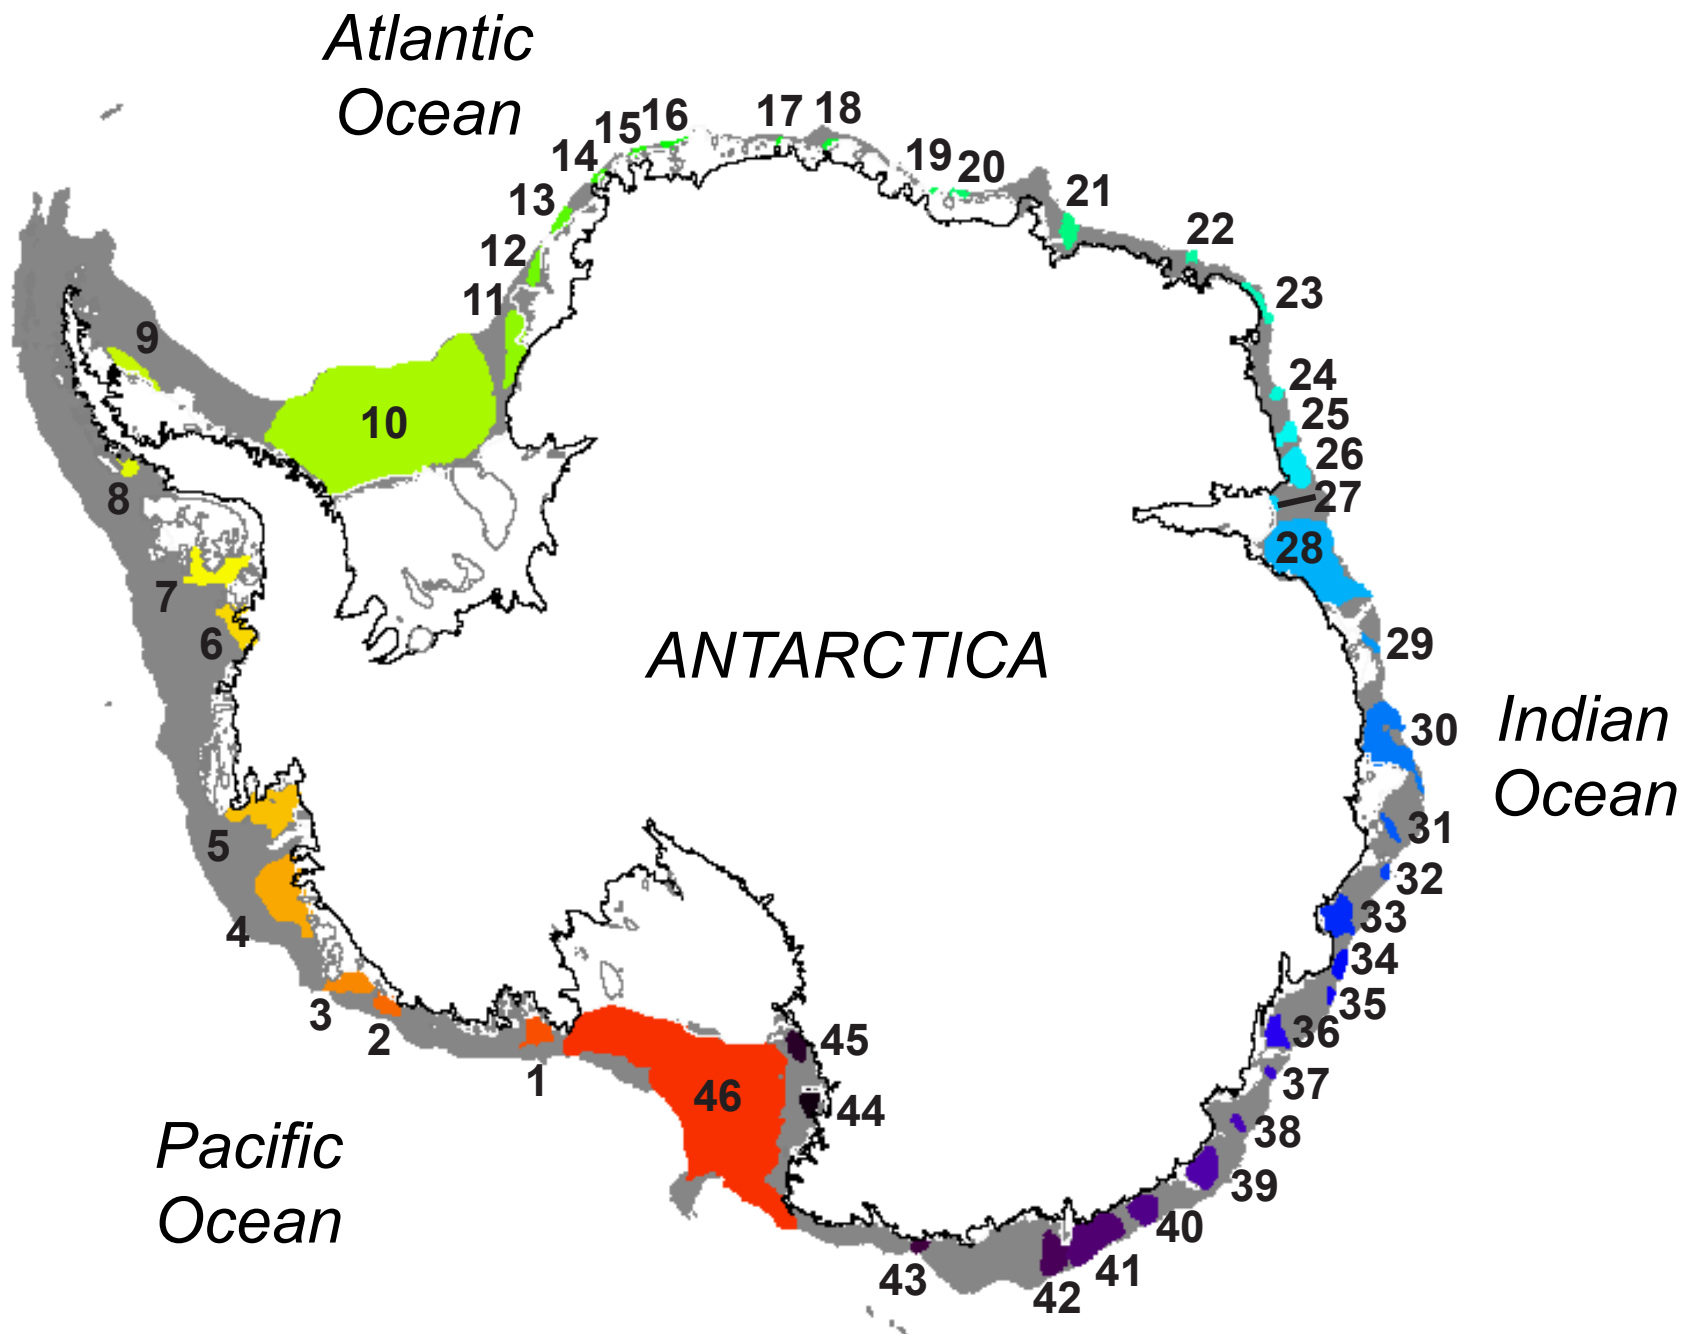

Phaeocystis antarctica

Approach

For 1998-2013:
Used satellite data to identify polynyas, track changes in sea ice, measure SST and chlorophyll *a* concentration, and calculate primary production

Annual mean phytoplankton abundance in 46 coastal polynyas

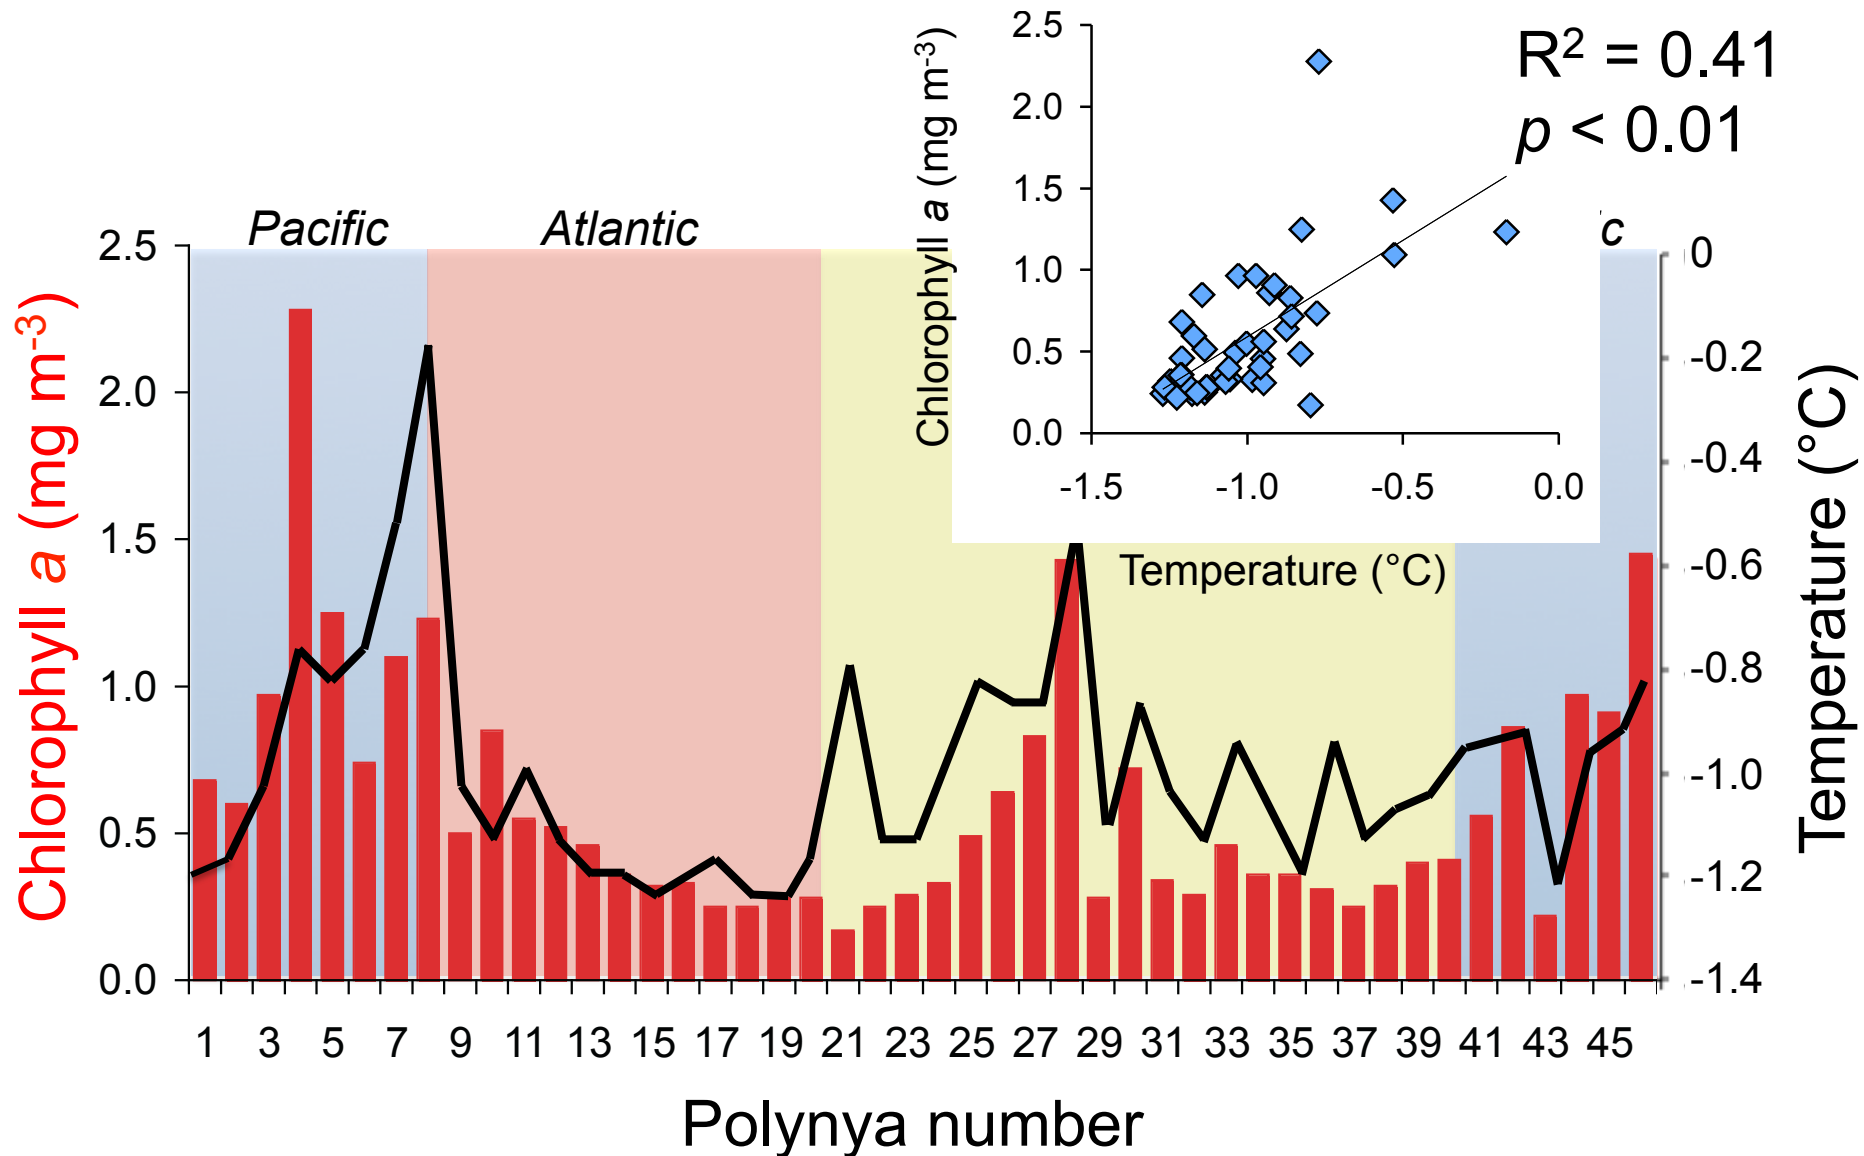

Annual mean phytoplankton abundance in 46 coastal polynyas

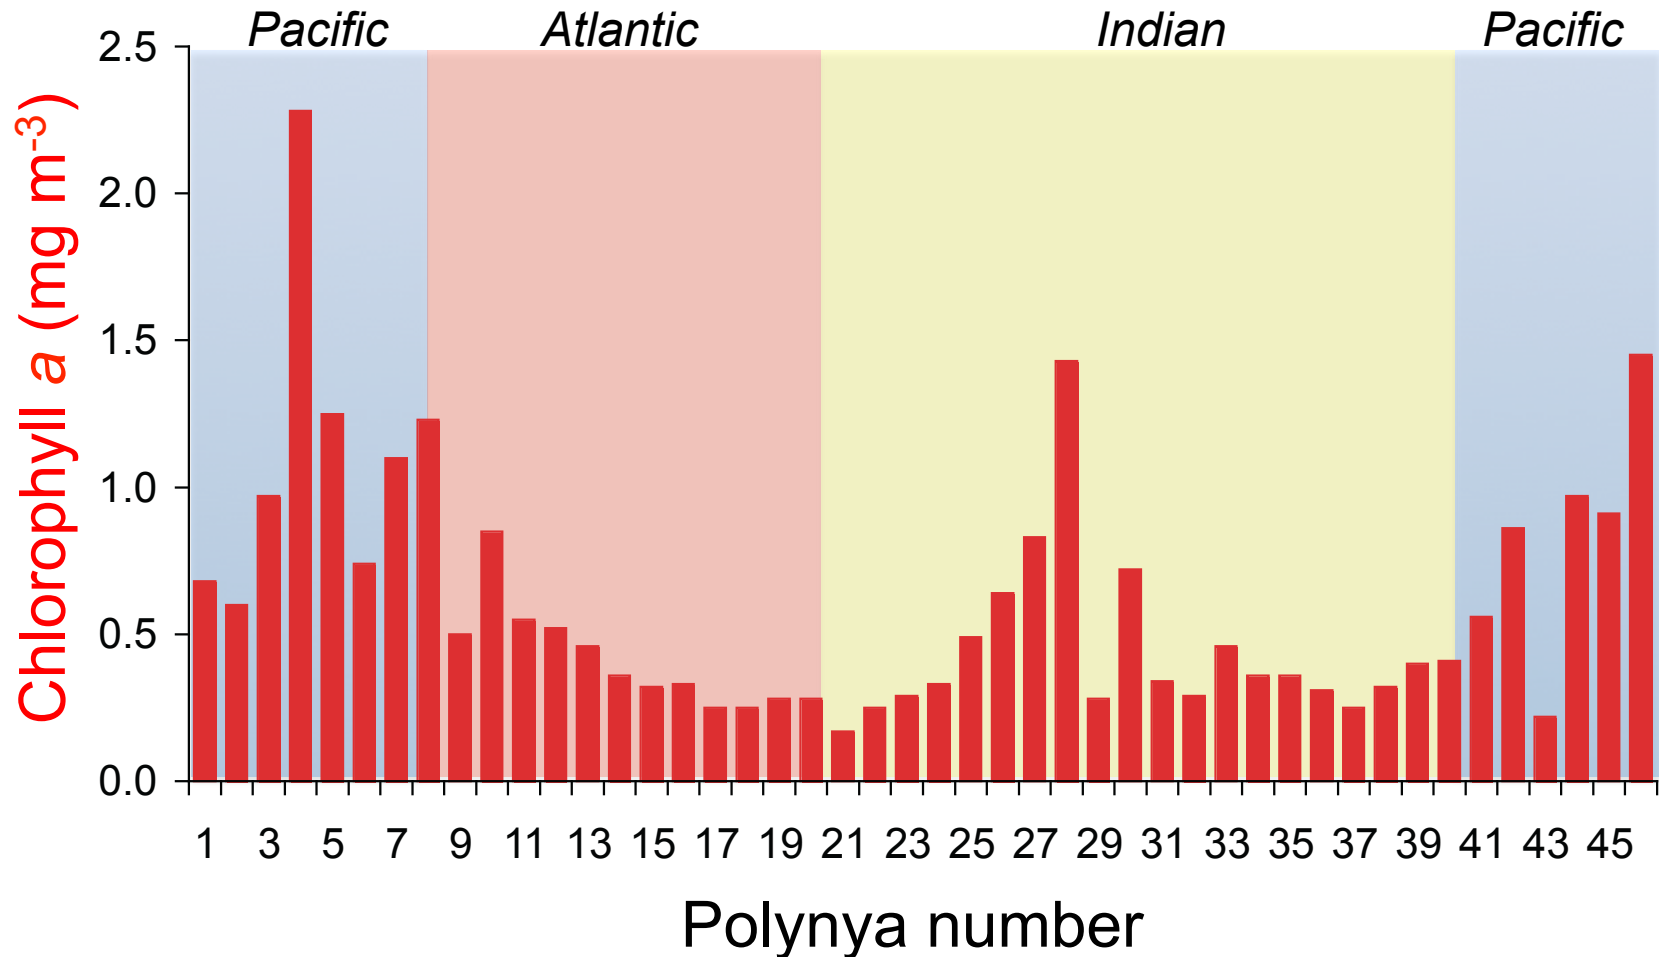

- Related to annual mean sea surface temperature
- Warmer temperatures promote higher Chl *a*
- Strongest relationship in Atlantic sector

Annual mean phytoplankton abundance in 46 coastal polynyas

What other factors control phytoplankton abundance in coastal polynyas?

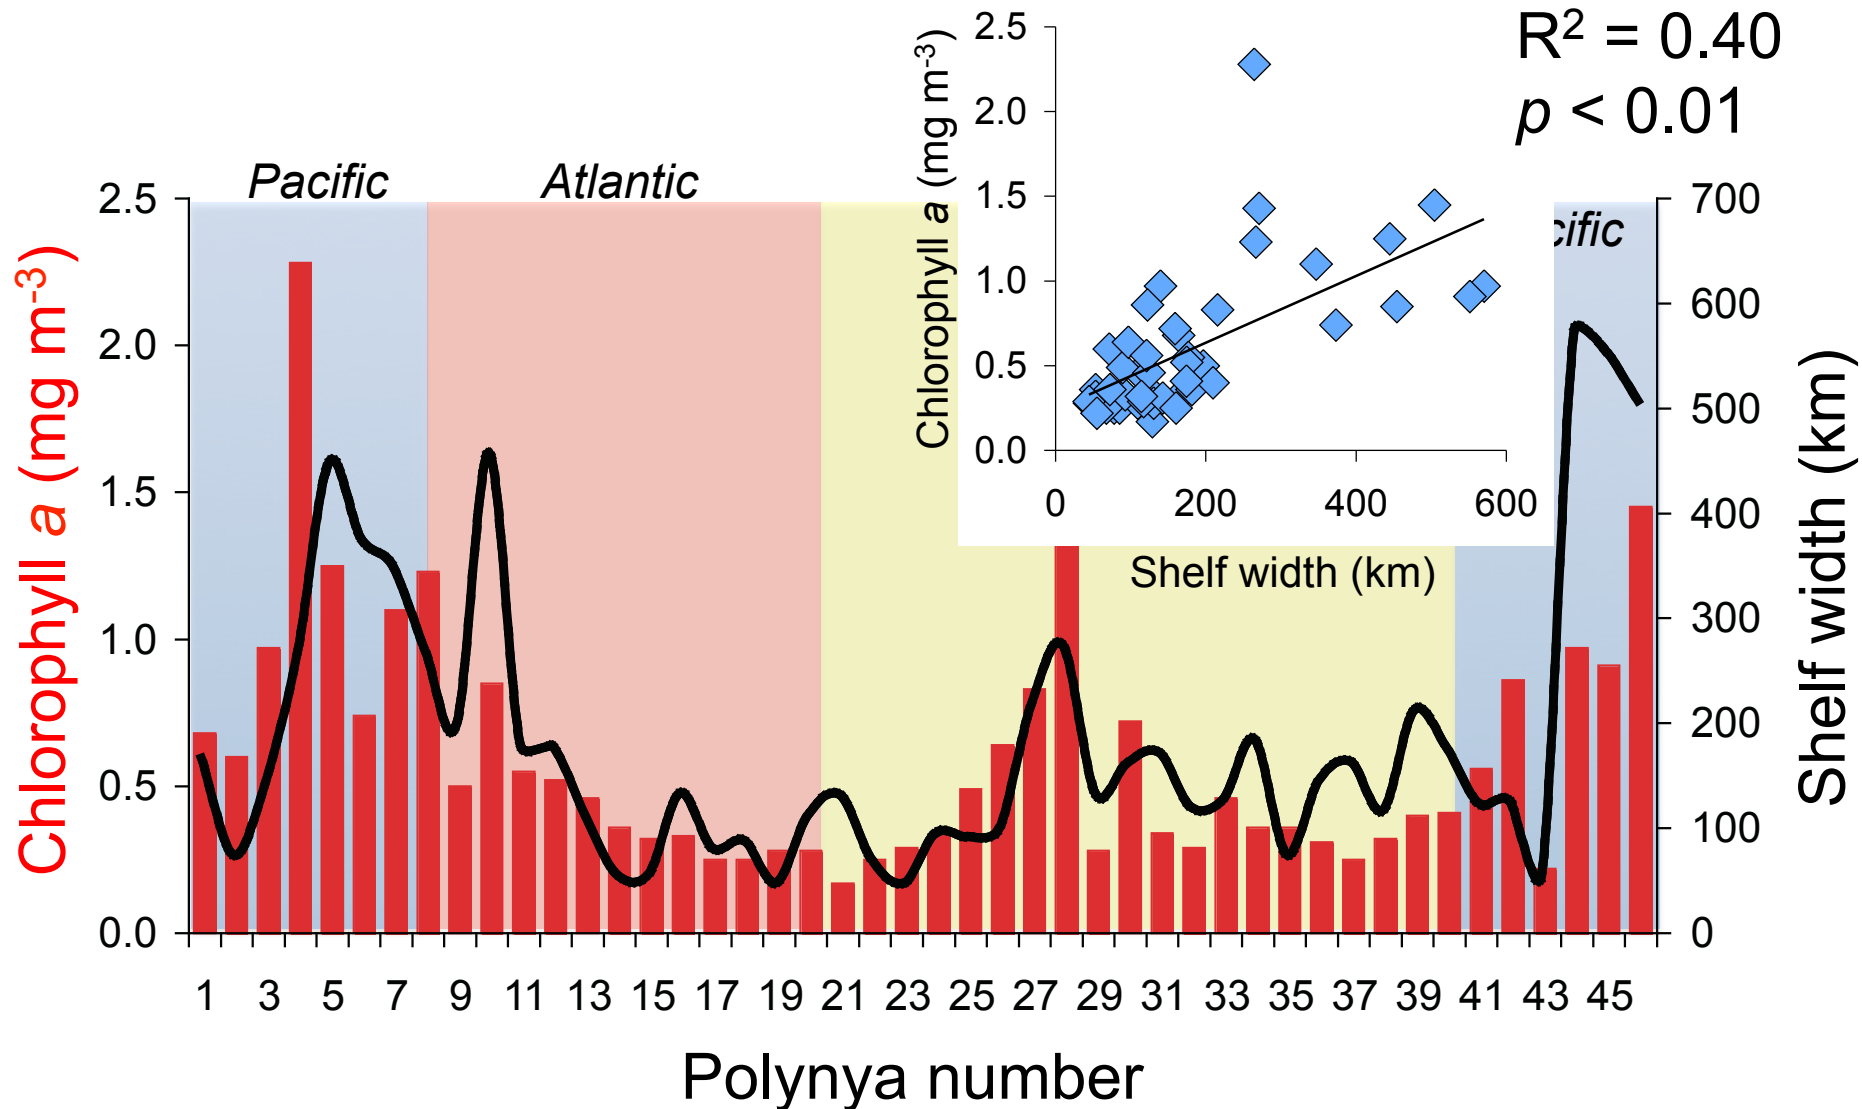

What other factors control phytoplankton abundance in coastal polynyas?

- Related to width of local continental shelf
- Relationship about equally strong in all sectors

What other factors control phytoplankton abundance in coastal polynyas?

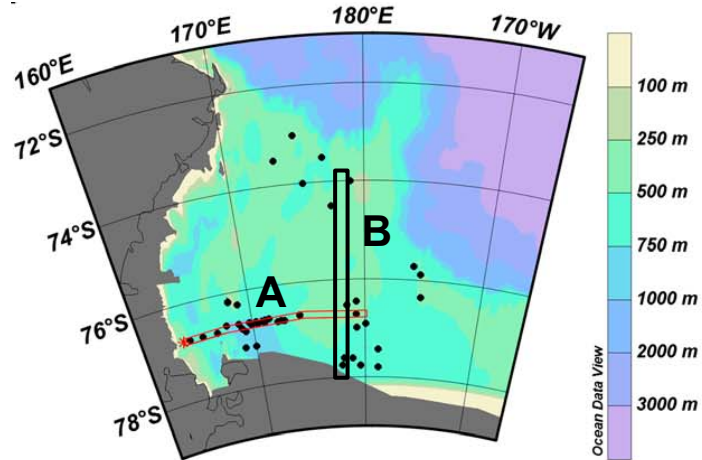

Why the relationship between phytoplankton abundance and continental shelf width?

- Highest seawater iron concentrations are on the shelf
- Wider shelves have larger iron inventory and permit greater entrainment of iron into surface waters (Bruland et al. 2005, Biller et al. 2013)
- More iron = higher phytoplankton biomass

Blue = Low iron concentration
Orange = High iron concentration

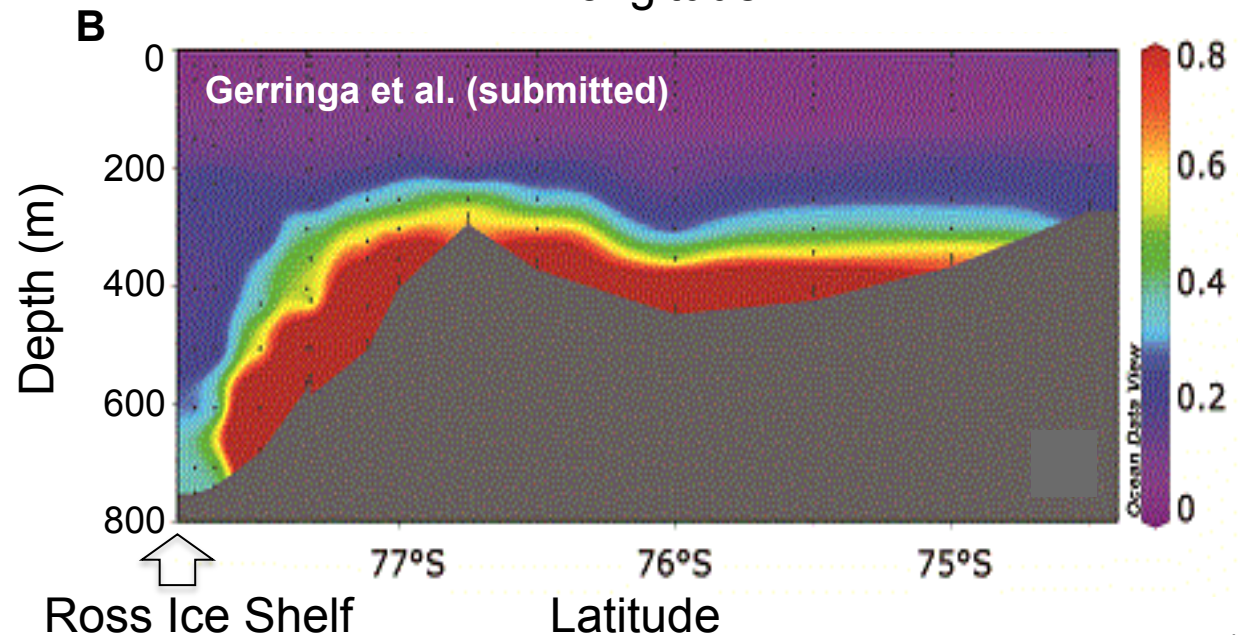

Why the relationship between phytoplankton abundance and continental shelf width?

Best example is in
Ross Sea

Large continental
shelf

Low Fe near RIS

What other factors control phytoplankton abundance in coastal polynyas?

What other factors control phytoplankton abundance in coastal polynyas?

- 39 of 46 coastal polynyas are adjacent to melting ice shelves

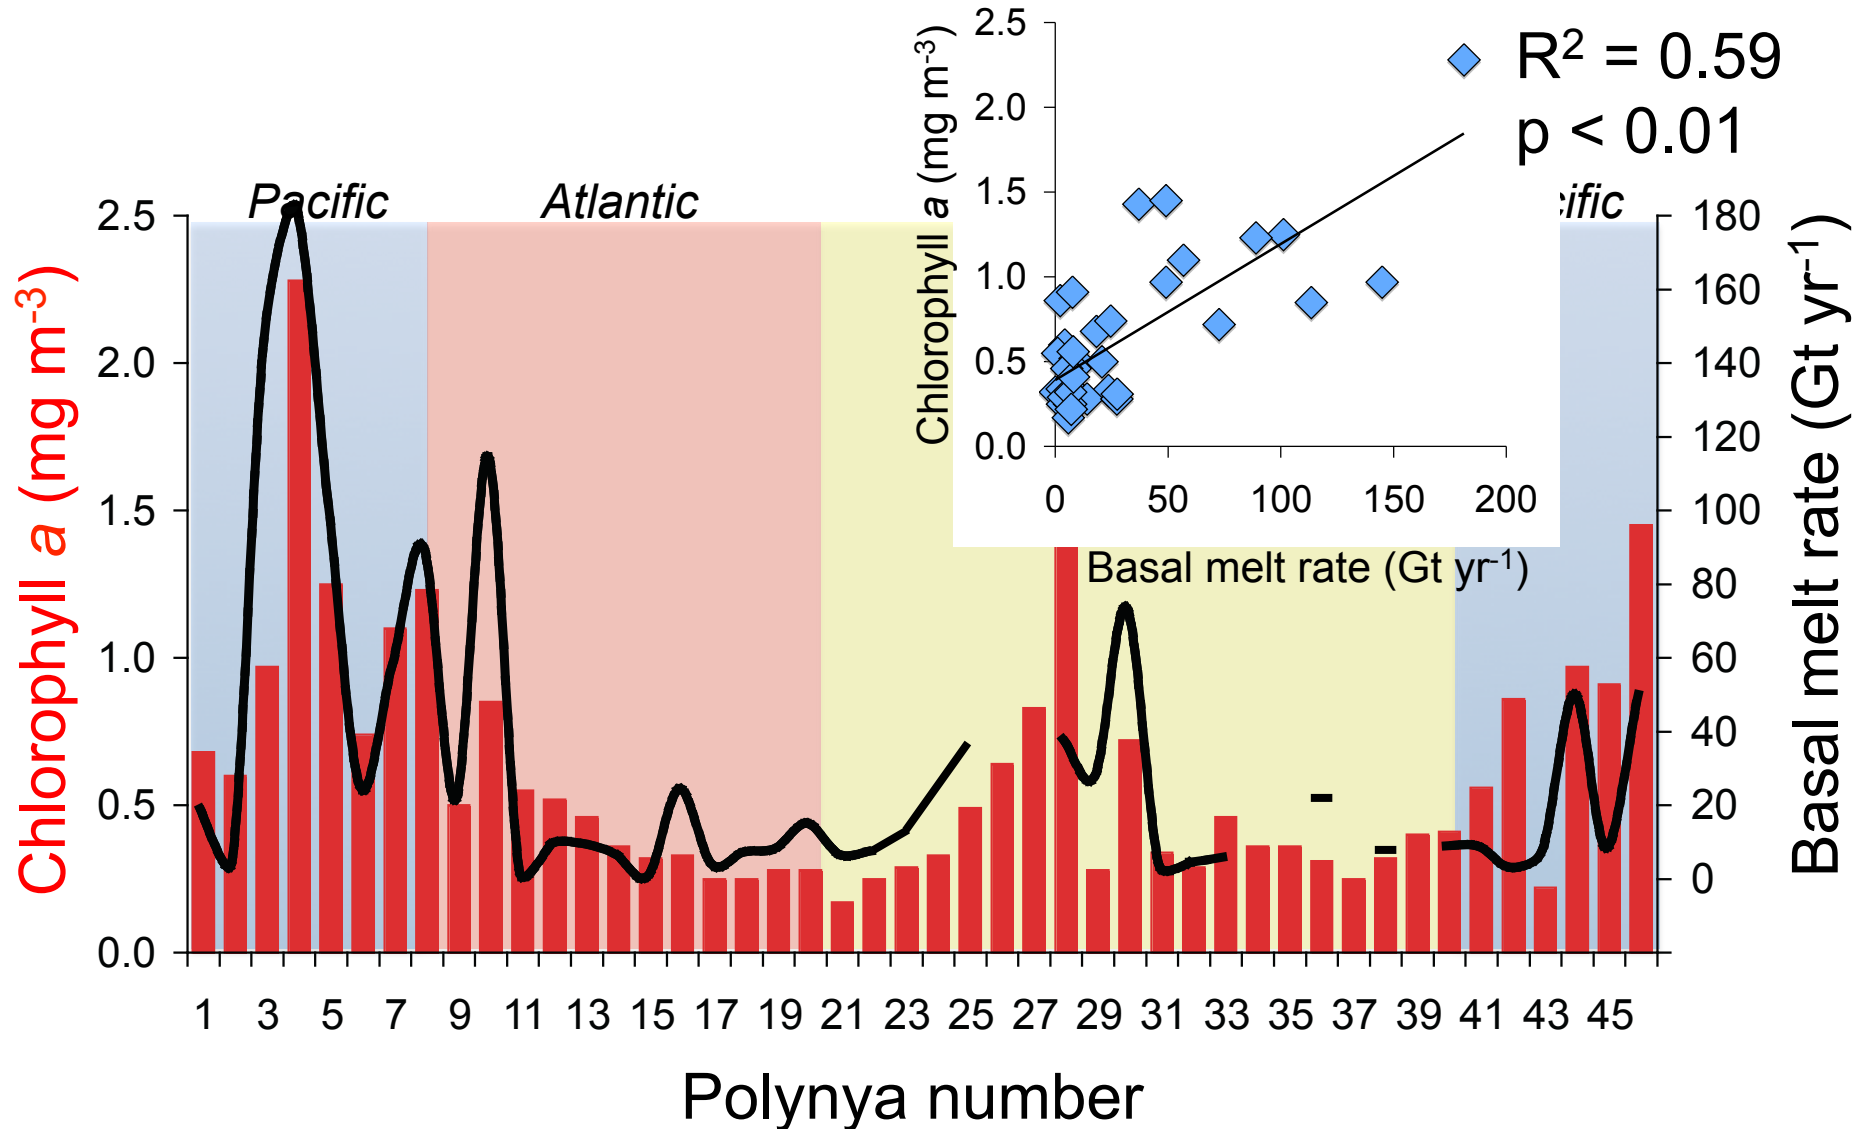

What other factors control phytoplankton abundance in coastal polynyas?

- 39 of 46 coastal polynyas are adjacent to melting ice shelves
- Phytoplankton abundance related to basal melt rate
- Relationship strongest in Pacific sector

What other factors control phytoplankton abundance in coastal polynyas?

Why the relationship between phytoplankton abundance and basal melt rate of nearby ice shelves?

- Ice sheets grind up bedrock as they flow to sea
- Ice sheets accumulate Fe-containing dust
- Particulate and dissolved iron is released into seawater
- Facilitated by upwelling of warm CDW
- Iron taken up by growing phytoplankton

Why the relationship between phytoplankton abundance and basal melt rate of nearby ice shelves?

Best example is in Amundsen Sea

- Most rapidly melting glaciers
- Large Fe flux at face of Pine Island Glacier
- Fe consumed by phytoplankton in surface waters

How much variance in chlorophyll *a* can be explained by environmental variables?

Multiple regression model included:

Shelf width

SST

Basal melt rate

Open water area

*Number of days of open water

*Mean daily PAR

*Removed because they had no effect on regression model

Some of the predictor variables were significantly but weakly correlated

Predictor	Predictor	R ²	<i>p</i> -value
Shelf width	SST	0.19	$p < 0.01$
SST	Basal melt	0.16	$p < 0.01$
Shelf width	Basal melt	0.17	$p < 0.01$
Shelf width	Open water	0.20	$p < 0.01$

Multiple linear regression: $R^2 = 0.77$

Parameter	<i>p</i> -value	VIF	% of R^2 explained
Basal melt rate (Gt yr ⁻¹)	<0.001	1.34	43.6%
Sea surface temp (°C)	<0.01	1.42	24.5%
Shelf width (km)	<0.01	1.67	19.1%
Mean open water (km ²)	<0.05	1.26	12.8%

VIF = Variance Inflation Factor (should be below 2.5)

CONCLUSIONS

Even coastal Antarctic polynyas are iron-limited
Light does not control phytoplankton productivity

Higher SST increases phytoplankton abundance directly through increased growth rates but possibly also indirectly through increased glacial melting

Wide shelves are more productive than narrow ones
Greater resuspension of sediment iron

Very productive polynyas require input of glacial meltwater
Presumably because of additional iron supplies

Future increases in glacial melt are likely to increase biological productivity of coastal ecosystems
